Additional Content/Ideas/Info Provided By:

- Jon A. Erickson, Christian Arllen, Dave Keppler
- Who suggested what, is inline with the material

About Me

- Security nerd - generalist, not specialist
- Realmz ~1996, Mac OS 8, BEQ->BNE FTW!
- x86 ~2002
- Know or have known ~5 assembly languages (x86, SPARC, ARM, PPC, 68HC12). x86 is by far the most complex.
- Routinely read assembly when debugging my own code, reading exploit code, and reverse engineering things

About You?

- Name & Department
- Why did you want to take the class?
- If you know you will be applying this knowledge, to which OS and/or development environment?

About the Class

- The intent of this class is to expose you to the most commonly generated assembly instructions, and the most frequently dealt with architecture hardware.
  - 32 bit instructions/hardware
  - Implementation of a Stack
  - Common tools
- Many things will therefore be left out or deferred to later classes.
  - Floating point instructions/hardware
  - 16/64 bit instructions/hardware
  - Complicated or rare 32 bit instructions
  - Instruction pipeline, caching hierarchy, alternate modes of operation, hw virtualization, etc

About the Class 2

- The hope is that the material covered will be provide the required background to delve deeper into areas which may have seemed daunting previously.
- Because I can't anticipate the needs of all job classes, if there are specific areas which you think would be useful to certain job types, let me know. The focus areas are currently primarily influenced by my security background, but I would like to make the class as widely applicable as possible.

Agenda

- Day 1 - Part 1 - Architecture Introduction, Windows tools
- Day 1 - Part 2 - Windows Tools & Analysis, Learning New Instructions
- Day 2 - Part 1 - Linux Tools & Analysis
- Day 2 - Part 2 - Inline Assembly, Read The Fun Manual, Choose Your Own Adventure

Miss Alaineous

- Questions: Ask ‘em if you got ‘em
  - If you fall behind and get lost and try to tough it out until you understand, it’s more likely that you will stay lost, so ask questions ASAP.
- Browsing the web and/or checking email during class is a good way to get lost ;)
- Vote on class schedule.
- Benevolent dictator clause.
- It’s called x86 because of the progression of Intel chips from 8086, 80186, 80286, etc. I just had to get that out of the way. :)

What you're going to learn

```
#include <stdio.h>
int main(){
    printf("Hello World!\n");
    return 0x1234;
}
```

Is the same as…

```
.text:00401730 main
.text:00401730                 push    ebp
.text:00401731                 mov     ebp, esp
.text:00401733                 push    offset aHelloWorld ; "Hello world\n"
.text:00401738                 call    ds:__imp__printf
.text:0040173E                 add     esp, 4
.text:00401741                 mov     eax, 1234h
.text:00401746                 pop     ebp
.text:00401747                 retn
```

Windows Visual C++ 2005, /GS (buffer overflow protection) option turned off
Disassembled with IDA Pro 4.9 Free Version

Is the same as…

```
08048374 <main>:
 8048374:       8d 4c 24 04                   lea    0x4(%esp),%ecx
 8048378:       83 e4 f0                      and    $0xfffffff0,%esp
 804837b:       ff 71 fc                      pushl  -0x4(%ecx)
 804837e:       55                            push   %ebp
 804837f:       89 e5                         mov    %esp,%ebp
 8048381:       51                            push   %ecx
 8048382:       83 ec 04                      sub    $0x4,%esp
 8048385:       c7 04 24 60 84 04 08          movl   $0x8048460,(%esp)
 804838c:       e8 43 ff ff ff                call   80482d4 <puts@plt>
 8048391:       b8 2a 00 00 00                mov    $0x1234,%eax
 8048396:       83 c4 04                      add    $0x4,%esp
 8048399:       59                            pop    %ecx
 804839a:       5d                            pop    %ebp
 804839b:       8d 61 fc                      lea    -0x4(%ecx),%esp
 804839e:       c3                            ret
 804839f:       90                            nop
```

Ubuntu 8.04, GCC 4.2.4
Disassembled with “objdump -d”

Is the same as…

```
_main:
00001fca        pushl   %ebp
00001fcb        movl    %esp,%ebp
00001fcd        pushl   %ebx
00001fce        subl    $0x14,%esp
00001fd1        calll   0x00001fd6
00001fd6        popl    %ebx
00001fd7        leal    0x0000001a(%ebx),%eax
00001fdd        movl    %eax,(%esp)
00001fe0        calll   0x00003005      ; symbol stub for: _puts
00001fe5        movl    $0x00001234,%eax
00001fea        addl    $0x14,%esp
00001fed        popl    %ebx
00001fee        leave
00001fef        ret
```

Mac OS 10.5.6, GCC 4.0.1
Disassembled from command line with “otool -tV”

But it all boils down to…

```
.text:00401000 main
.text:00401000        push    offset aHelloWorld ; "Hello world\n"
.text:00401005        call    ds:__imp__printf
.text:0040100B        pop     ecx
.text:0040100C        mov     eax, 1234h
.text:00401011        retn
```

Windows Visual C++ 2005, /GS (buffer overflow protection) option turned off
Optimize for minimum size (/O1) turned on
Disassembled with IDA Pro 4.9 Free Version

Take Heart!

- By one measure, only 14 assembly instructions account for 90% of code!
  - http://www.blackhat.com/presentations/bh-usa-06/BH-US-06-Bilar.pdf
- I think that knowing about 20-30 (not counting variations) is good enough that you will have the check the manual very infrequently
- You've already seen 11 instructions, just in the hello world variations!

Refresher - Data Types

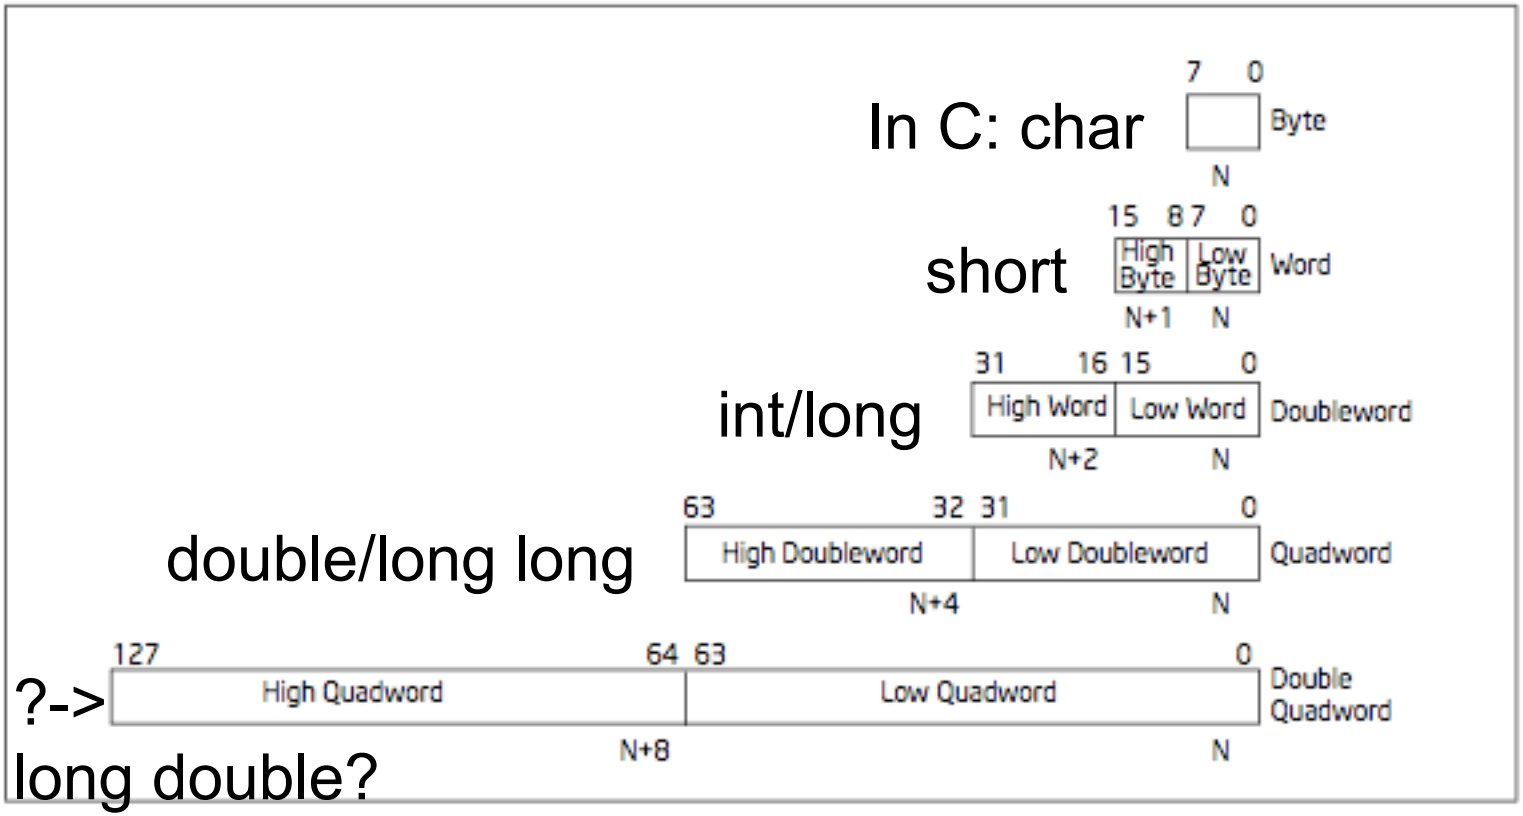

Figure 4-1. Fundamental Data Types

Refresher - Alt. Radices Decimal, Binary, Hexidecimal

If you don't know this, you must memorize tonight

Decimal (base 10)	Binary (base 2)	Hex (base 16)
00	0000b	0x00
01	0001b	0x01
02	0010b	0x02
03	0011b	0x03
04	0100b	0x04
05	0101b	0x05
06	0110b	0x06
07	0111b	0x07
08	1000b	0x08
09	1001b	0x09
10	1010b	0x0A
11	1011b	0x0B
12	1100b	0x0C
13	1101b	0x0D
14	1110b	0x0E
15	1111b	0x0F

Refresher - Negative Numbers

- “one’s complement” = flip all bits. 0->1, 1->0
- “two’s complement” = one’s complement + 1
- Negative numbers are defined as the “two’s complement” of the positive number

Number	One’s Comp.	Two’s Comp. (negative)
00000001b : 0x01	11111110b : 0xFE	11111111b : 0xFF : -1
00000100b : 0x04	11111011b : 0xFB	11111100b : 0xFC : -4
00011010b : 0x1A	11100101b : 0xE5	11100110b : 0xE6 : -26
?	?	10110000b : 0xB0 : -?

- 0x01 to 0x7F positive byte, 0x80 to 0xFF negative byte
- 0x00000001 to 0x7FFFFFFF positive dword
- 0x80000000 to 0xFFFFFFFF negative dword

Architecture - CISC vs. RISC

- Intel is CISC - Complex Instruction Set Computer
  - Many very special purpose instructions that you will never see, and a given compiler may never use - just need to know how to use the manual
  - Variable-length instructions, between 1 and 16(?) bytes long.
    - 16 is max len in theory, I don't know if it can happen in practice
- Other major architectures are typically RISC - Reduced Instruction Set Computer
  - Typically more registers, less and fixed-size instructions
  - Examples: PowerPC, ARM, SPARC, MIPS

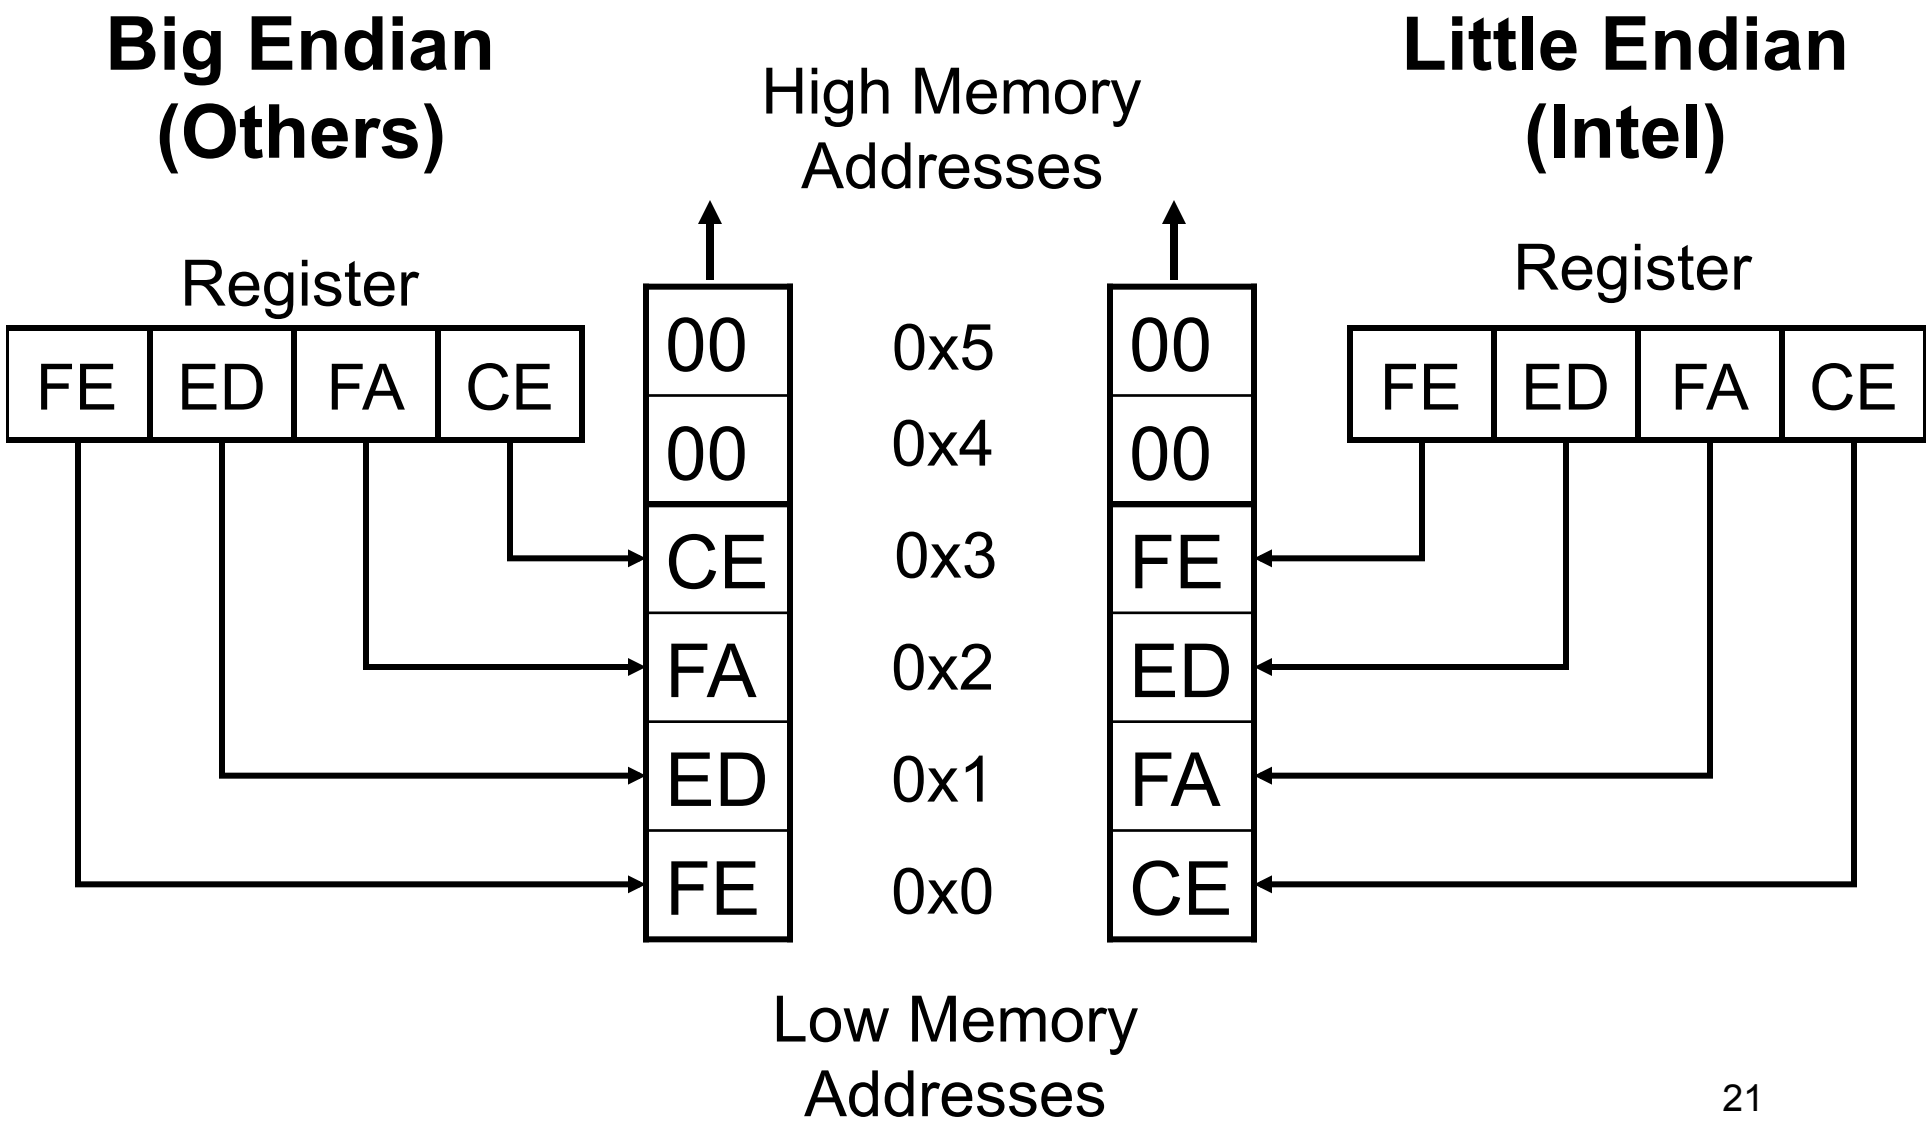
Architecture - Endian

- Endianness comes from Jonathan Swift's *Gulliver's Travels*. It doesn't matter which way you eat your eggs :)
- Little Endian - 0x12345678 stored in RAM "little end" first. The least significant byte of a word or larger is stored in the lowest address. E.g. 0x78563412
  - Intel is Little Endian
- Big Endian - 0x12345678 stored as is.
  - Network traffic is Big Endian
  - Most everyone else you've heard of (PowerPC, ARM, SPARC, MIPS) is either Big Endian by default or can be configured as either (Bi-Endian)

Book p. 163

Book for this class is "Professional Assembly Language" by Blum

Endianess pictures



Architecture - Registers

- Registers are small memory storage areas built into the processor (still volatile memory)
- 8 “general purpose” registers + the instruction pointer which points at the next instruction to execute
  - But two of the 8 are not that general
- On x86-32, registers are 32 bits long
- On x86-64, they’re 64 bits

Book p. 25

Architecture - Register Conventions 1

- These are Intel's suggestions to compiler developers (and assembly handcoders). Registers don't have to be used these ways, but if you see them being used like this, you'll know why. But I simplified some descriptions. I also color coded as **GREEN** for the ones which we will actually see in *this* class (as opposed to future ones), and **RED** for not.
- **EAX** – Stores function return values
- **EBX** – Base pointer to the data section
- **ECX** – Counter for string and loop operations
- **EDX** – I/O pointer

Intel Arch v1 Section 3.4.1 - General-Purpose Registers

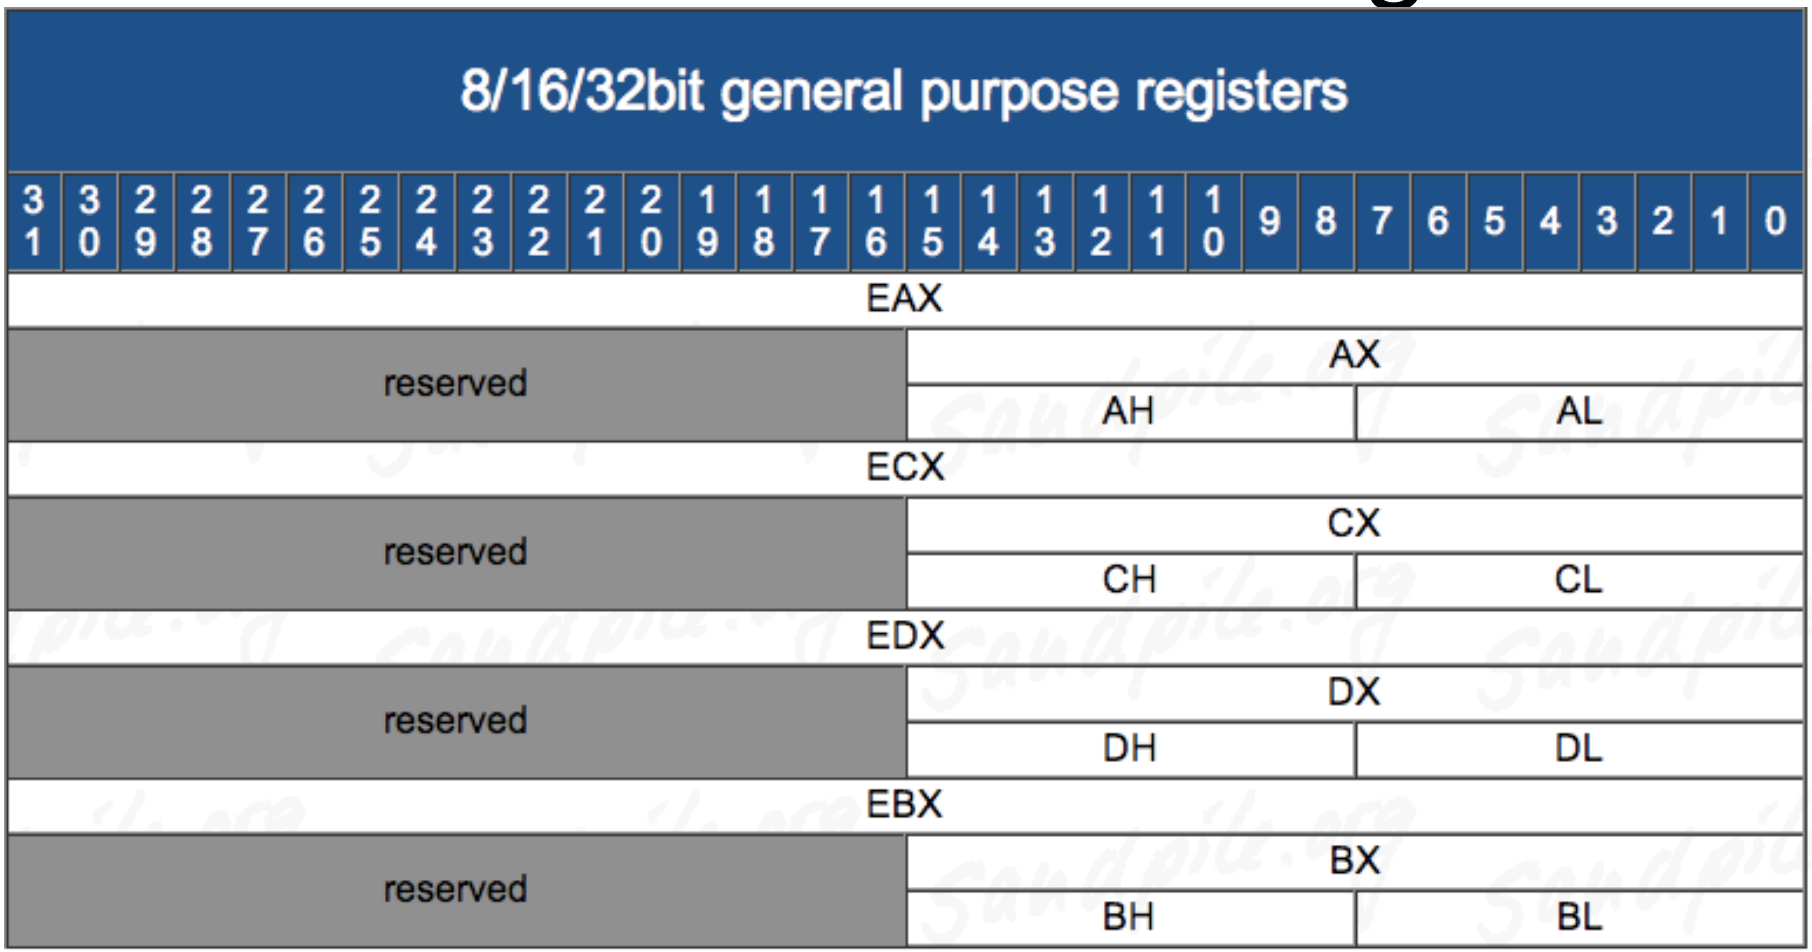
Architecture - Registers Conventions 2

- **ESI** – Source pointer for string operations
- **EDI** – Destination pointer for string operations
- **ESP** – Stack pointer
- **EBP** – Stack frame base pointer
- **EIP** - Pointer to next instruction to execute (“instruction pointer”)

Architecture - Registers Conventions 3

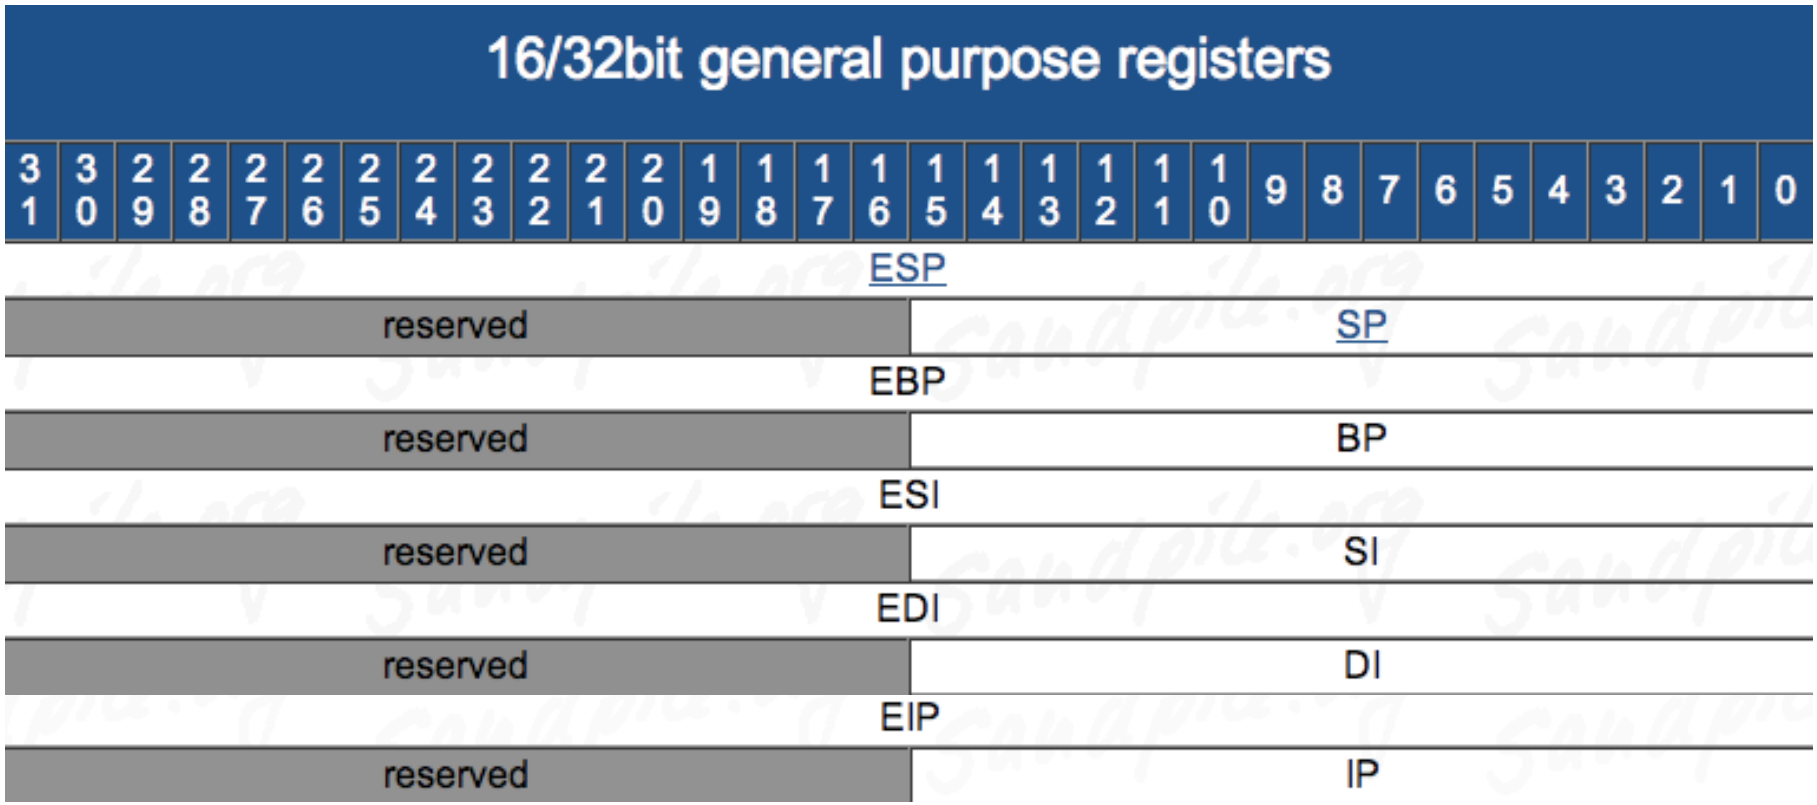
- Caller-save registers - eax, edx, ecx
  - If the caller has anything in the registers that it cares about, the caller is in charge of saving the value before a call to a subroutine, and restoring the value after the call returns
  - Put another way - the callee can (and is highly likely to) modify values in caller-save registers
- Callee-save registers - ebp, ebx, esi, edi
  - If the callee needs to use more registers than are saved by the caller, the callee is responsible for making sure the values are stored/restored
  - Put another way - the callee must be a good citizen and not modify registers which the caller didn't save, unless the callee itself saves and restores the existing values

Architecture - Registers - 8/16/32 bit addressing 1



http://www.sandpile.org/ia32/reg.htm

Architecture - Registers - 8/16/32 bit addressing 2



http://www.sandpile.org/ia32/reg.htm

Architecture - EFLAGS

- EFLAGS register holds many single bit flags. Will only ask you to remember the following for now.
  - Zero Flag (ZF) - Set if the result of some instruction is zero; cleared otherwise.
  - Sign Flag (SF) - Set equal to the most-significant bit of the result, which is the sign bit of a signed integer. (0 indicates a positive value and 1 indicates a negative value.)

Intel Vol 1 Sec 3.4.3 - page 3-20

Your first x86 instruction: NOP

- NOP - No Operation! No registers, no values, no nothin'!
- Just there to pad/align bytes, or to delay time
- Bad guys use it to make simple exploits more reliable. But that's another class ;)

Extra! Extra! Late-breaking NOP news!

- Amaze those who know x86 by citing this interesting bit of trivia:
- "The one-byte NOP instruction is an alias mnemonic for the XCHG (E)AX, (E)AX instruction."
  - I had never looked in the manual for NOP apparently :)
- Every other person I had told this to had never heard it either.
- Thanks to Jon Erickson for cluing me in to this.
- XCHG instruction is not officially in this class. But if I hadn't just told you what it does, I bet you would have guessed right anyway.

XCHG in book p. 112

The Stack

- The stack is a conceptual area of main memory (RAM) which is designated by the OS when a program is started.
  - Different OS start it at different addresses by convention
- A stack is a Last-In-First-Out (LIFO/FILO) data structure where data is "pushed" on to the top of the stack and "popped" off the top.
- By convention the stack grows toward lower memory addresses. Adding something to the stack means the top of the stack is now at a lower memory address.

The Stack 2

- As already mentioned, esp points to the top of the stack, the lowest address which is being used
  - While data will exist at addresses beyond the top of the stack, it is considered undefined
- The stack keeps track of which functions were called before the current one, it holds local variables and is frequently used to pass arguments to the next function to be called.
- A firm understanding of what is happening on the stack is ***essential*** to understanding a program's operation.

PUSH - Push Word, Doubleword or Quadword onto the Stack

- For our purposes, it will always be a DWORD (4 bytes).
  - Can either be an immediate (a numeric constant), or the value in a register
- The push instruction automatically decrements the stack pointer, esp, by 4.

Book p. 120

Registers Before

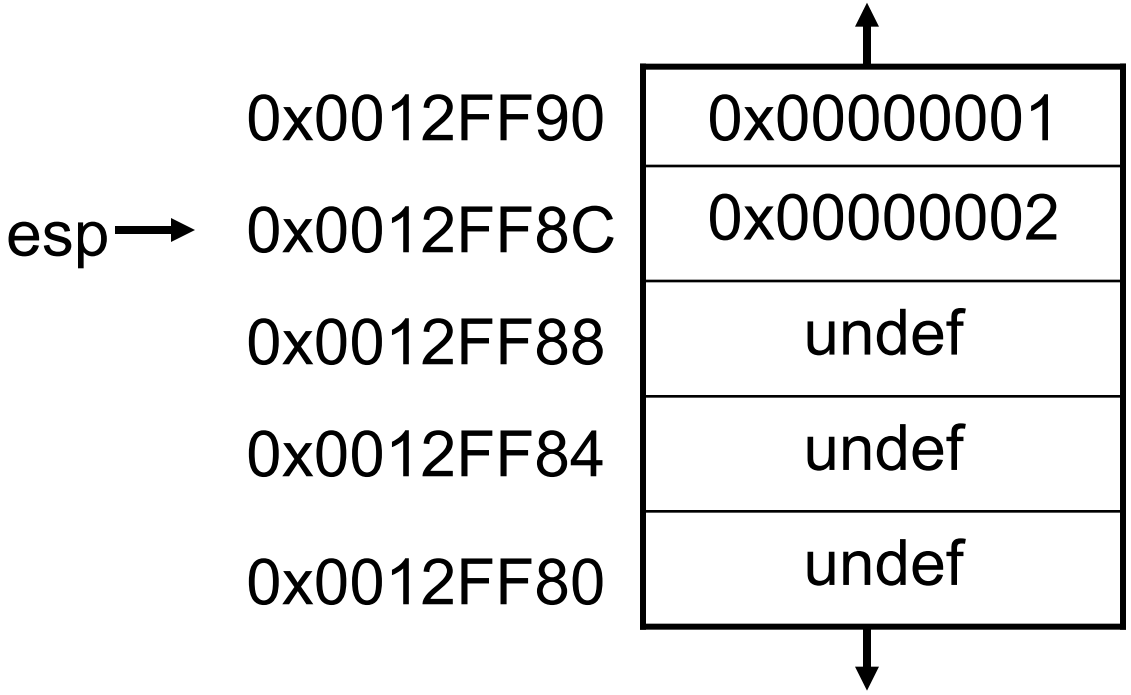
eax	0x00000003
esp	0x0012FF8C

push eax

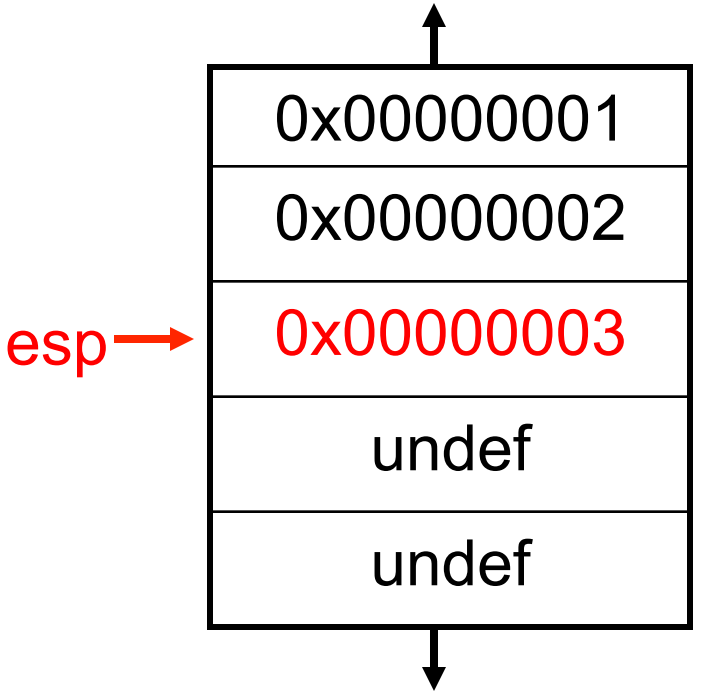
Registers After

eax	0x00000003
esp	0x0012FF88

Stack Before



Stack After



POP- Pop a Value from the Stack

- Take a DWORD off the stack, put it in a register, and increment esp by 4

Book p. 120

Registers Before

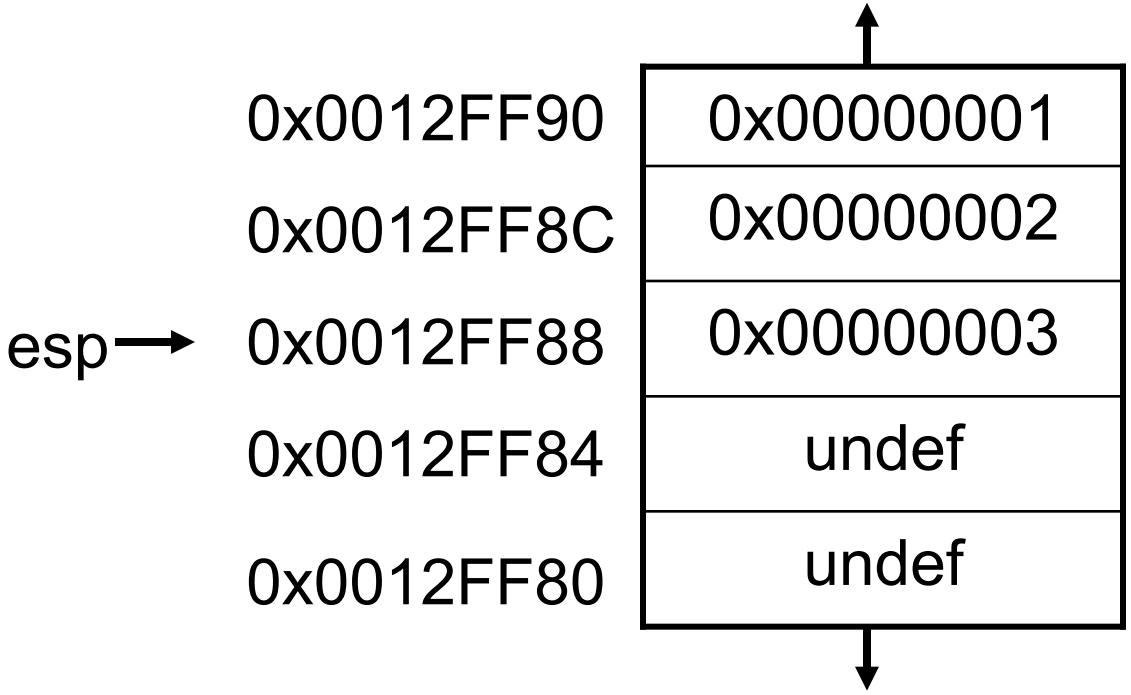
eax	0xFFFFFFFF
esp	0x0012FF88

pop eax

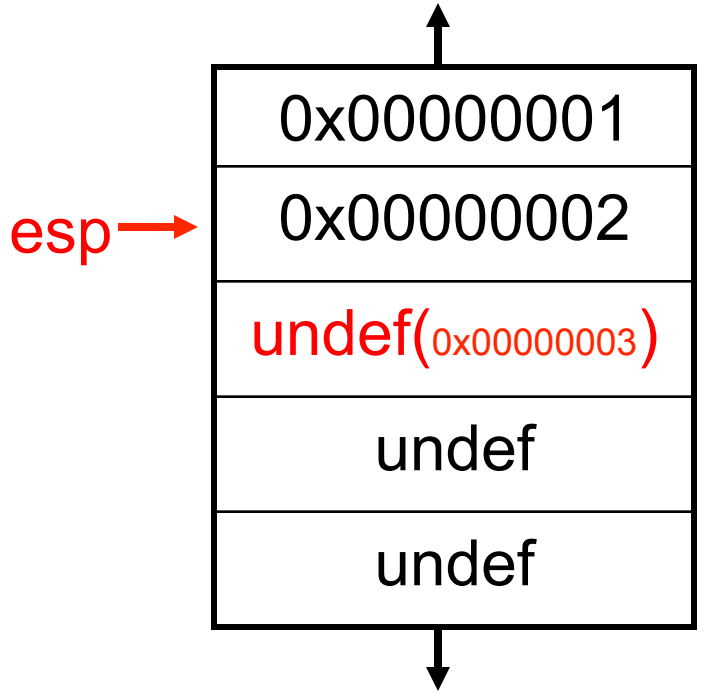
Registers After

eax	0x00000003
esp	0x0012FF8C

Stack Before



Stack After



Calling Conventions

- How code calls a subroutine is compiler-dependent and configurable. But there are a few conventions.
- We will only deal with the “cdecl” and “stdcall” conventions.
- More info at
  - http://en.wikipedia.org/wiki/X86_calling_conventions
  - http://www.programmersheaven.com/2/Calling-conventions

Calling Conventions - cdecl

- “C declaration” - most common calling convention
- Function parameters pushed onto stack right to left
- Saves the old stack frame pointer and sets up a new stack frame
- eax or edx:eax returns the result for primitive data types
- Caller is responsible for cleaning up the stack

Calling Conventions - stdcall

- I typically only see this convention used by Microsoft C++ code - e.g. Win32 API
- Function parameters pushed onto stack right to left
- Saves the old stack frame pointer and sets up a new stack frame
- eax or edx:eax returns the result for primitive data types
- Callee responsible for cleaning up any stack parameters it takes
- Aside: typical MS, “If I call my new way of doing stuff ‘standard’ it must be true!”

CALL - Call Procedure

- CALL's job is to transfer control to a different function, in a way that control can later be resumed where it left off
- First it pushes the address of the next instruction onto the stack
  - For use by RET for when the procedure is done
- Then it changes eip to the address given in the instruction
- Destination address can be specified in multiple ways
  - Absolute address
  - Relative address (relative to the end of the instruction)

Book p. 132

RET - Return from Procedure

- Two forms
  - Pop the top of the stack into eip (remember pop increments stack pointer)
    - In this form, the instruction is just written as “ret”
    - Typically used by cdecl functions
  - Pop the top of the stack into eip and add a constant number of bytes to esp
    - In this form, the instruction is written as “ret 0x8”, or “ret 0x20”, etc
    - Typically used by stdcall functions

Kinda book p. 133

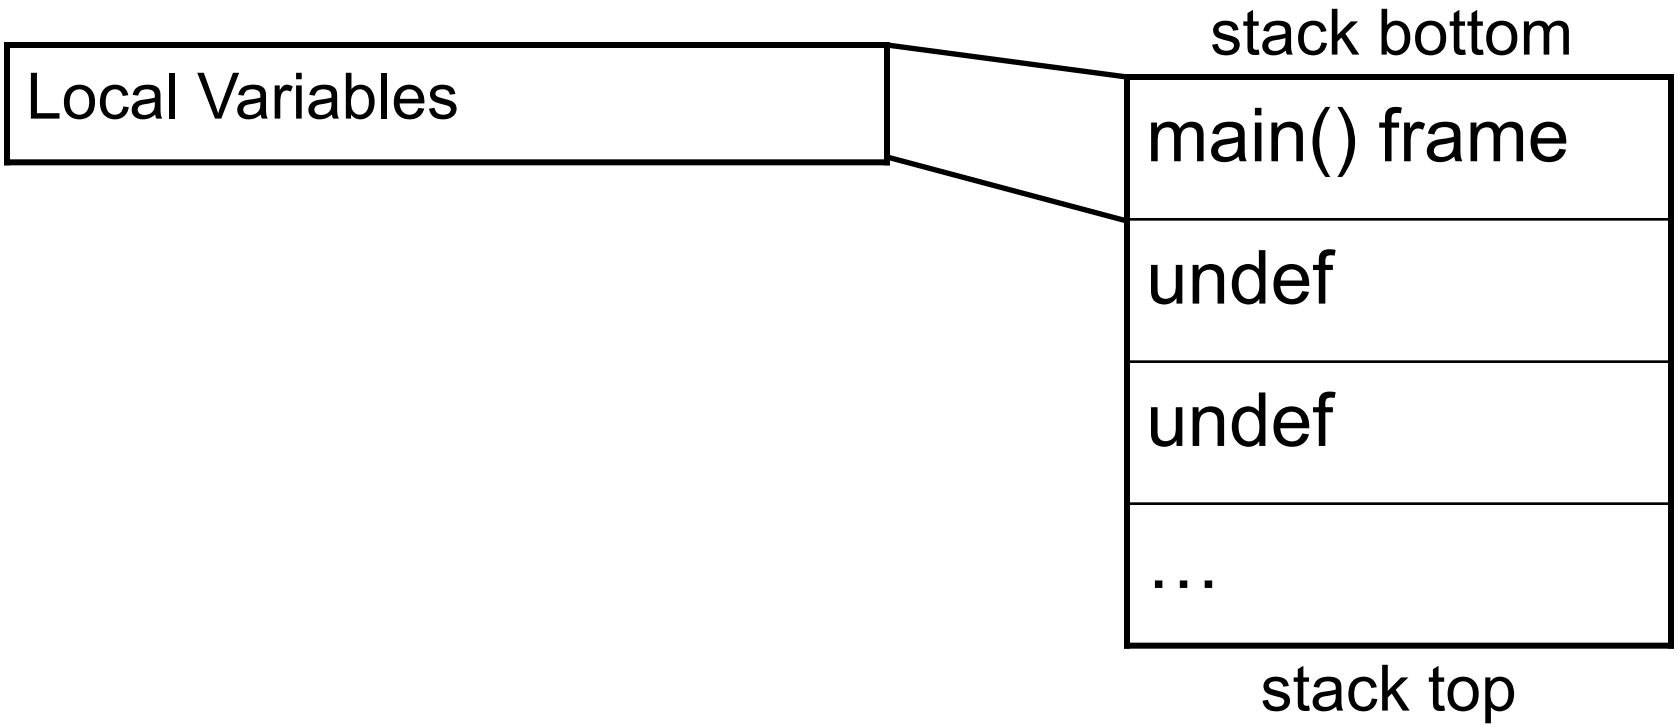
MOV - Move

- Can move:
  - register to register
  - memory to register, register to memory
  - immediate to register, immediate to memory
- Never memory to memory!
- Memory addresses are given in r/m32 form talked about later

Book p. 97

General Stack Frame Operation

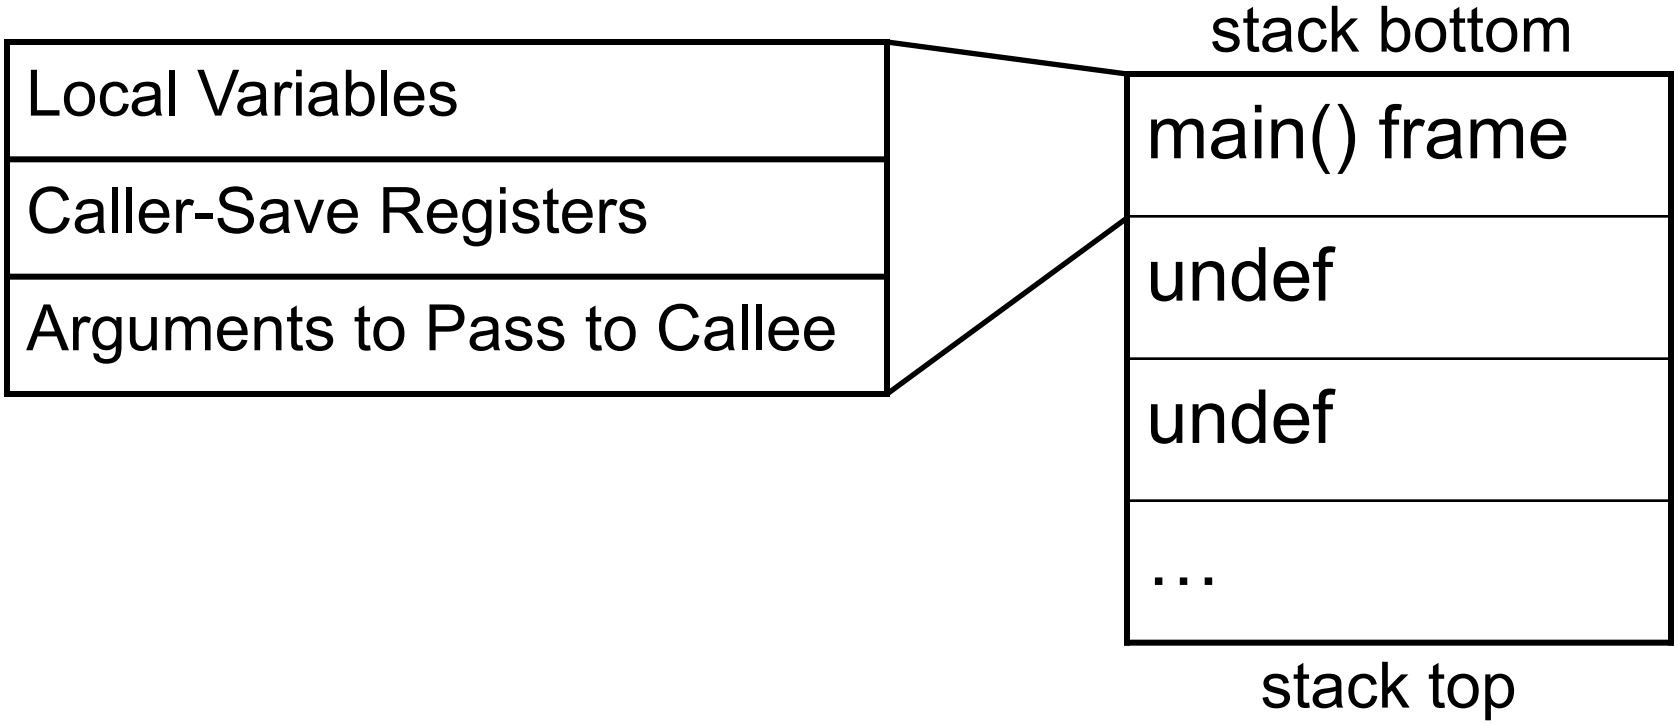
We are going to pretend that main() is the very first function being executed in a program. This is what its stack looks like to start with (assuming it has any local variables).



Book p. 306

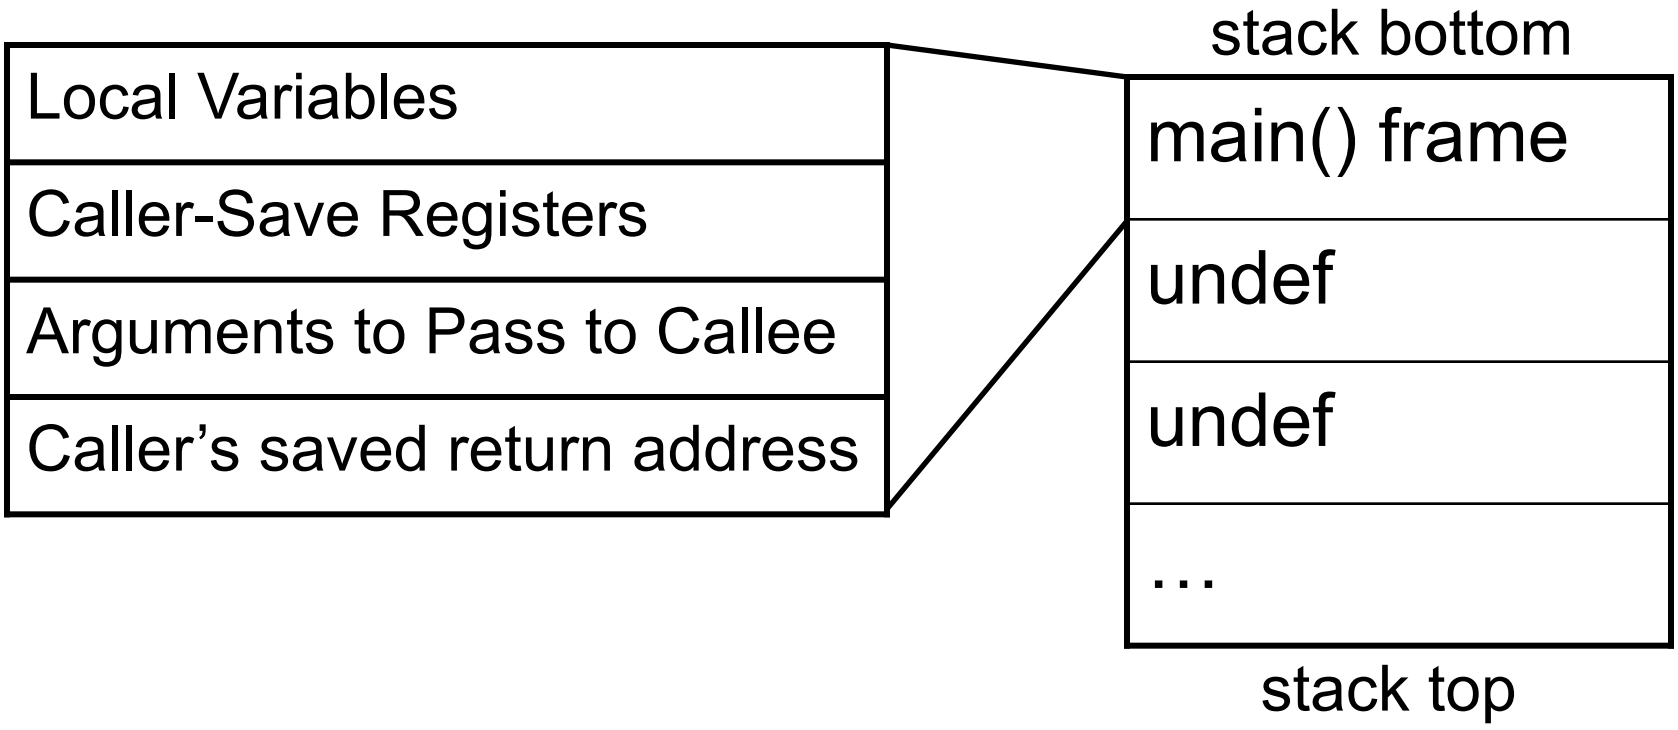
General Stack Frame Operation 2

When main() decides to call a subroutine, main() becomes “the caller”. We will assume main() has some registers it would like to remain the same, so it will save them. We will also assume that the callee function takes some input arguments.



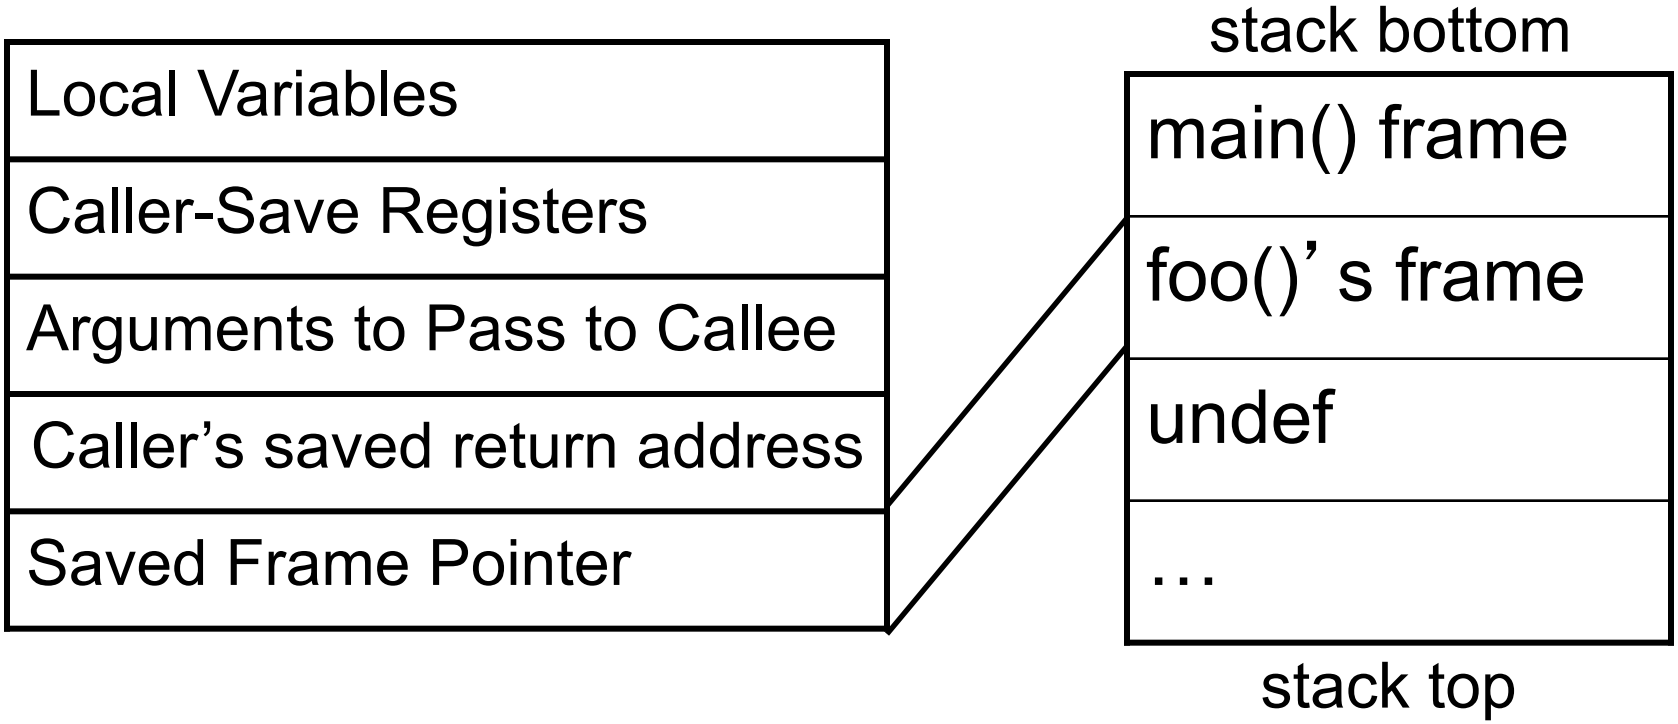
General Stack Frame Operation 3

When main() actually issues the CALL instruction, the return address gets saved onto the stack, and because the next instruction after the call will be the beginning of the called function, we consider the frame to have changed to the callee.



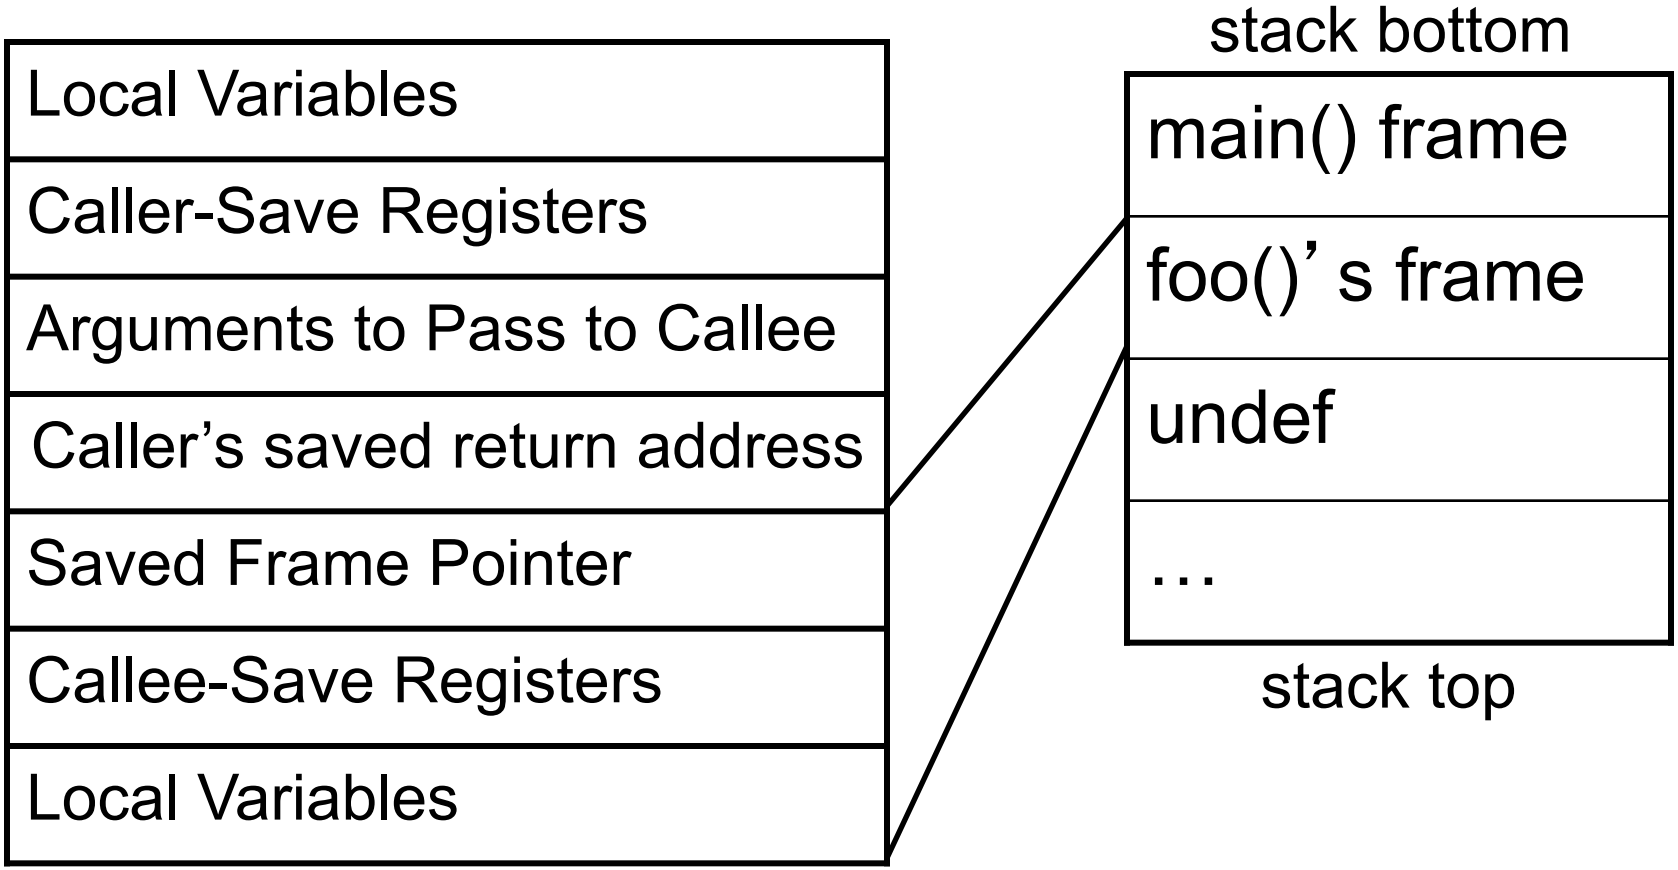
General Stack Frame Operation 4

When sub() starts, the frame pointer (ebp) still points to main()'s frame. So the first thing it does is to save the old frame pointer on the stack and set the new value to point to its own frame.



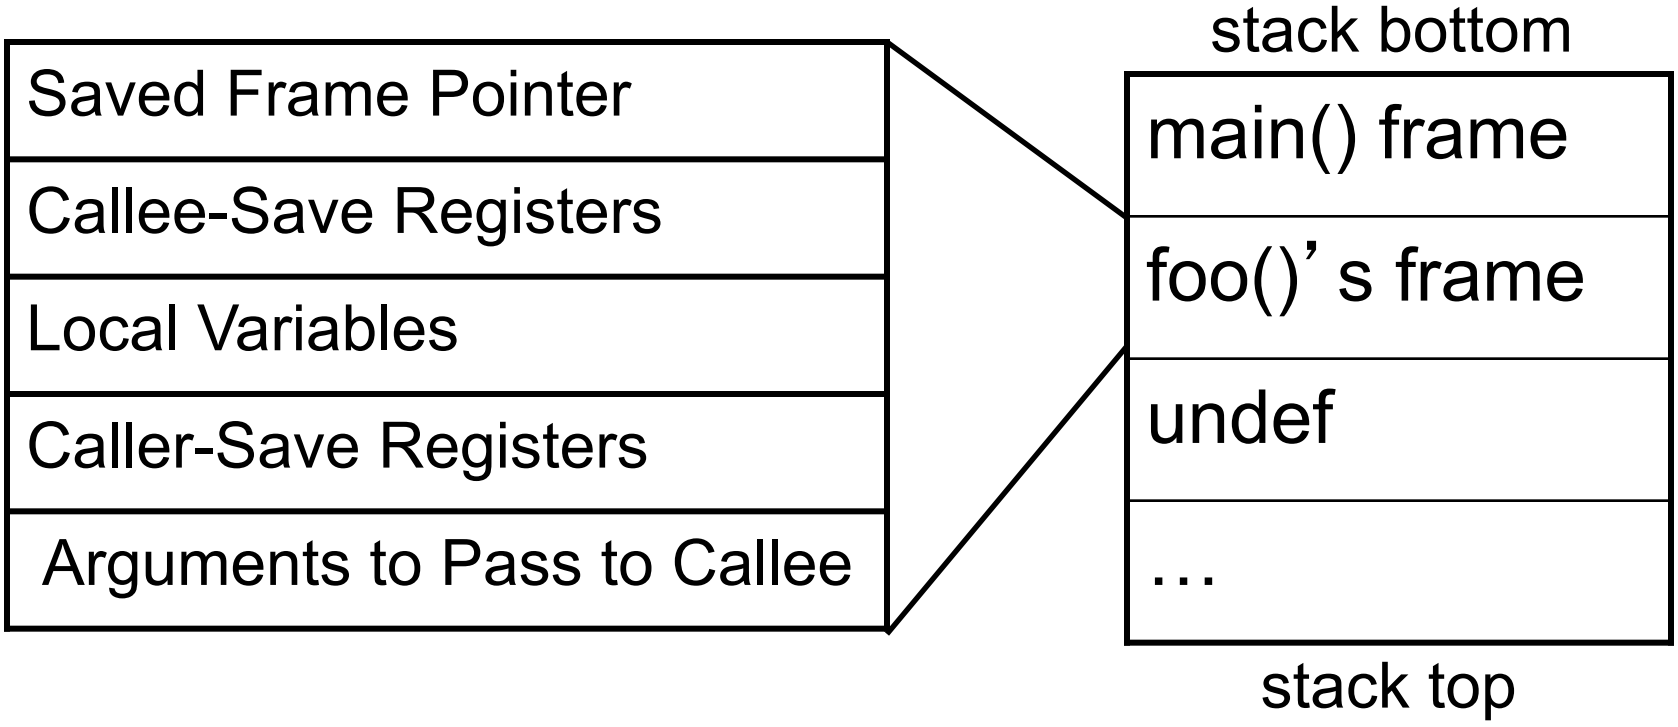
General Stack Frame Operation 5

Next, we'll assume the the callee sub() would like to use all the registers, and must therefore save the callee-save registers. Then it will allocate space for its local variables.



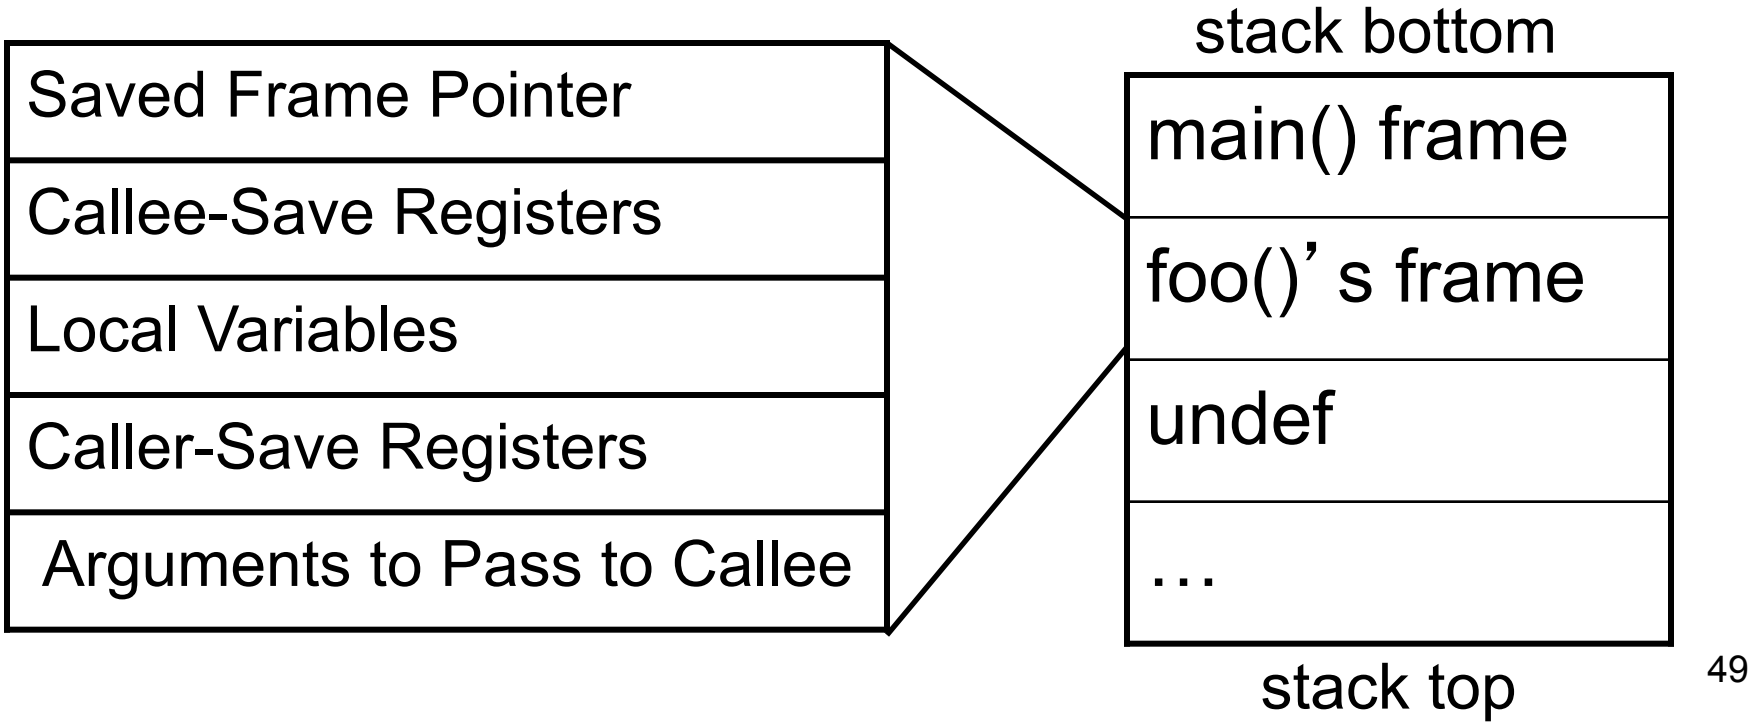
General Stack Frame Operation 6

At this point, foo() decides it wants to call bar(). It is still the callee-of-main (), but it will now be the caller-of-bar. So it saves any caller-save registers that it needs to. It then puts the function arguments on the stack as well.



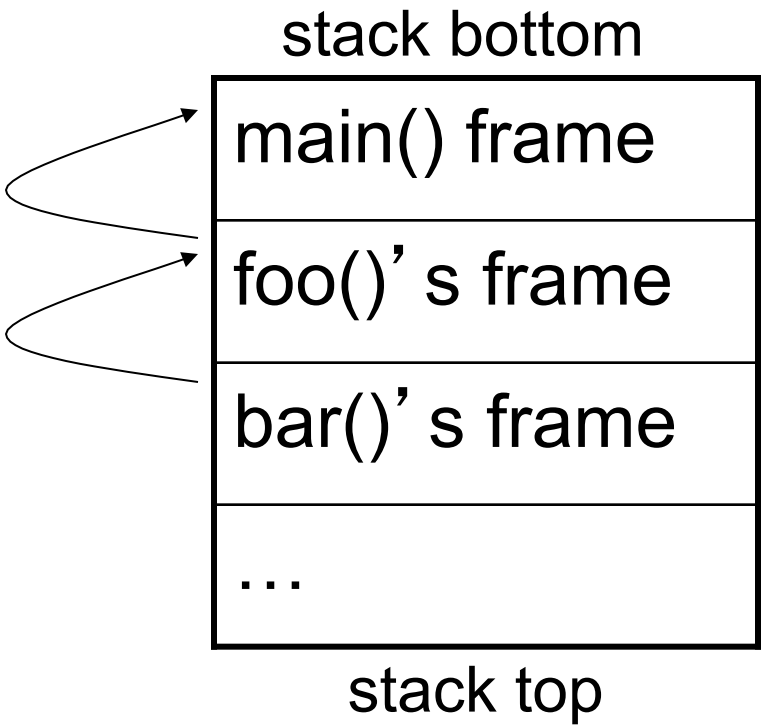
General Stack Frame Layout

Every part of the stack frame is technically optional (that is, you can hand code asm without following the conventions.)
But compilers generate code which uses portions if they are needed.
Which pieces are used can sometimes be manipulated with compiler options. (E.g. omit frame pointers, changing calling convention to pass arguments in registers, etc.)



Stack Frames are a Linked List!

The ebp in the current frame points at the saved ebp of the previous frame.



Example1.c

The stack frames in this example will be very simple.
Only saved frame pointer (ebp) and saved return addresses (eip).

```
//Example1 - using the stack
//to call subroutines
//New instructions:
//push, pop, call, ret, mov
int sub(){
    return 0xbeef;
}
int main(){
    sub();
    return 0xf00d;
}
```

```
sub:
00401000  push        ebp
00401001  mov         ebp,esp
00401003  mov         eax,0BEEFh
00401008  pop         ebp
00401009  ret
main:
00401010  push        ebp
00401011  mov         ebp,esp
00401013  call        sub (401000h)
00401018  mov         eax,0F00Dh
0040101D  pop         ebp
0040101E  ret
```

Example1.c 1:

EIP = 0040103, but no instruction yet executed

0040101E  ret ☒
```

Execution would continue at the value ret removed from the stack: 0x004012E8

Example1 Notes

- sub() is deadcode - its return value is not used for anything, and main always returns 0xF00D. If optimizations are turned on in the compiler, it would remove sub()
- Because there are no input parameters to sub (), there is no difference whether we compile as cdecl vs stdcall calling conventions

Let's do that in a tool

- Visual C++ 2008 Express Edition (which I will shorthand as "VisualStudio" or VS)
- Standard Windows development environment
- Available for free, but missing some features that pro developers might want
- Can't move applications to other systems without installing the "redistributable libraries"

Unfortunately the debug information format alters the code which gets generated too much, making it not as simple as I would like for this class.

Going through Example1.c in Visual Studio

```
sub:
  push      ebp
  mov       ebp,esp
  mov       eax,0BEEFh
  pop       ebp
  ret
main:
  push      ebp
  mov       ebp,esp
  call      sub
  mov       eax,0F00Dh
  pop       ebp
  ret
```

Example2.c with Input parameters and Local Variables

```
#include <stdlib.h>
int sub(int x, int y){
        return 2*x+y;
}

int main(int argc, char ** argv){
        int a;
        a = atoi(argv[1]);
        return sub(argc,a);
}
```

```
.text:00000000 _sub:      push   ebp
.text:00000001            mov    ebp, esp
.text:00000003            mov    eax, [ebp+8]
.text:00000006            mov    ecx, [ebp+0Ch]
.text:00000009            lea    eax, [ecx+eax*2]

.text:0000002E            push   eax
.text:0000002F            call   _sub
.text:00000034            add    esp, 8
.text:00000037            mov    esp, ebp
.text:00000039            pop    ebp
.text:0000003A            retn
```

"r/m32" Addressing Forms

- Anywhere you see an r/m32 it means it could be taking a value either from a register, or a memory address.
- I'm just calling these "r/m32 forms" because anywhere you see "r/m32" in the manual, the instruction can be a variation of the below forms.
- In Intel syntax, most of the time square brackets [] means to treat the value within as a memory address, and fetch the value at that address (like dereferencing a pointer)
  - mov eax, ebx
  - mov eax, [ebx]
  - mov eax, [ebx+ecx*X] (X=1, 2, 4, 8)
  - mov eax, [ebx+ecx*X+Y] (Y= one byte, 0-255 or 4 bytes, 0-2^32-1)
- Most complicated form is: `[base + index*scale + disp]`

More info: Intel v2a, Section 2.1.5 page 2-4
in particular Tables 2-2 and 2-3

LEA - Load Effective Address

- Frequently used with pointer arithmetic, sometimes for just arithmetic in general
- Uses the r/m32 form but **is the exception to the rule** that the square brackets [ ] syntax means dereference (“value at”)
- Example: ebx = 0x2, edx = 0x1000
  - lea eax, [edx+ebx*2]
  - eax = 0x1004, not the value at 0x1004

Not covered in book

ADD and SUB

- Adds or Subtracts, just as expected
- Destination operand can be r/m32 or register
- Source operand can be r/m32 or register or immediate
- No source ***and*** destination as r/m32s, because that could allow for memory to memory transfer, which isn't allowed on x86
- Evaluates the operation as if it were on signed AND unsigned data, and sets flags as appropriate. Instructions modify OF, SF, ZF, AF, PF, and CF flags
- add esp, 8
- sub eax, [ebx*2]

Add p. 202, Sub p. 210

Example2.c - 1

```
.text:00000000 _sub:      push    ebp
.text:00000001            mov     ebp, esp
.text:00000003            mov     eax, [ebp+8]
.text:00000006            mov     ecx, [ebp+0Ch]
.text:00000009            lea     eax, [ecx+eax*2]
.text:0000000C            pop     ebp
.text:0000000D            retn

```

Caller-save, or space for local var? This time it turns out to be space for local var since there is no corresponding pop, and the address is used later to refer to the value we know is stored in a.

                        retn
```

Saving some slides…
This will push the address of the string at argv[1] (0x12FFD4). atoi() will read the string and turn in into an int, put that int in eax, and return. Then the adding 4 to esp will negate the having pushed the input parameter and make 0x12FF1C undefined again (this is indicative of cdecl)

```

First setting "a" equal to the return value. Then pushing "a" as the second parameter in sub(). We can see an obvious optimization would have been to replace the last two instructions with "push eax".

Additional Content/Ideas/Info Provided By:

- Jon A. Erickson, Christian Arllen, Dave Keppler
- Who suggested what, is inline with the material

About Me

- Security nerd - generalist, not specialist
- Realmz ~1996, Mac OS 8, BEQ->BNE FTW!
- x86 ~2002
- Know or have known ~5 assembly languages (x86, SPARC, ARM, PPC, 68HC12). x86 is by far the most complex.
- Routinely read assembly when debugging my own code, reading exploit code, and reverse engineering things

About You?

- Name & Department
- Why did you want to take the class?
- If you know you will be applying this knowledge, to which OS and/or development environment?

About the Class

- The intent of this class is to expose you to the most commonly generated assembly instructions, and the most frequently dealt with architecture hardware.
  - 32 bit instructions/hardware
  - Implementation of a Stack
  - Common tools
- Many things will therefore be left out or deferred to later classes.
  - Floating point instructions/hardware
  - 16/64 bit instructions/hardware
  - Complicated or rare 32 bit instructions
  - Instruction pipeline, caching hierarchy, alternate modes of operation, hw virtualization, etc

About the Class 2

- The hope is that the material covered will be provide the required background to delve deeper into areas which may have seemed daunting previously.
- Because I can't anticipate the needs of all job classes, if there are specific areas which you think would be useful to certain job types, let me know. The focus areas are currently primarily influenced by my security background, but I would like to make the class as widely applicable as possible.

Agenda

- Day 1 - Part 1 - Architecture Introduction, Windows tools
- Day 1 - Part 2 - Windows Tools & Analysis, Learning New Instructions
- Day 2 - Part 1 - Linux Tools & Analysis
- Day 2 - Part 2 - Inline Assembly, Read The Fun Manual, Choose Your Own Adventure

Miss Alaineous

- Questions: Ask ‘em if you got ‘em
  - If you fall behind and get lost and try to tough it out until you understand, it’s more likely that you will stay lost, so ask questions ASAP.
- Browsing the web and/or checking email during class is a good way to get lost ;)
- Vote on class schedule.
- Benevolent dictator clause.
- It’s called x86 because of the progression of Intel chips from 8086, 80186, 80286, etc. I just had to get that out of the way. :)

What you're going to learn

```
#include <stdio.h>
int main(){
    printf("Hello World!\n");
    return 0x1234;
}
```

Take Heart!

- By one measure, only 14 assembly instructions account for 90% of code!
  - http://www.blackhat.com/presentations/bh-usa-06/BH-US-06-Bilar.pdf
- I think that knowing about 20-30 (not counting variations) is good enough that you will have the check the manual very infrequently
- You've already seen 11 instructions, just in the hello world variations!

Refresher - Data Types

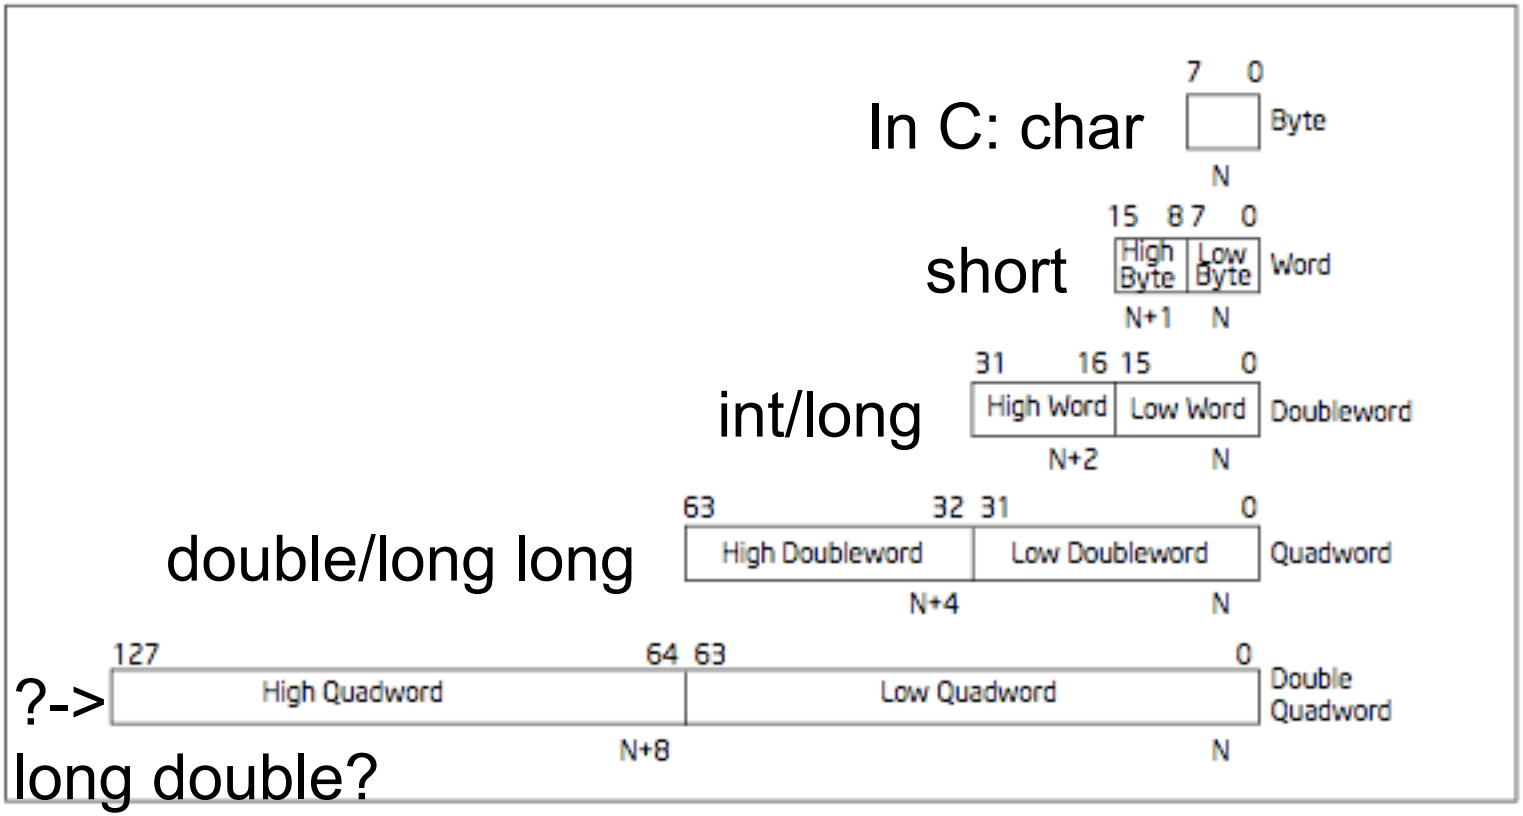

Figure 4-1. Fundamental Data Types

Refresher - Alt. Radices Decimal, Binary, Hexidecimal

If you don't know this, you must memorize tonight

Decimal (base 10)	Binary (base 2)	Hex (base 16)
00	0000b	0x00
01	0001b	0x01
02	0010b	0x02
03	0011b	0x03
04	0100b	0x04
05	0101b	0x05
06	0110b	0x06
07	0111b	0x07
08	1000b	0x08
09	1001b	0x09
10	1010b	0x0A
11	1011b	0x0B
12	1100b	0x0C
13	1101b	0x0D
14	1110b	0x0E
15	1111b	0x0F

Refresher - Negative Numbers

- "one's complement" = flip all bits. 0->1, 1->0
- "two's complement" = one's complement + 1
- Negative numbers are defined as the "two's complement" of the positive number

Number	One's Comp.	Two's Comp. (negative)
00000001b : 0x01	11111110b : 0xFE	11111111b : 0xFF : -1
00000100b : 0x04	11111011b : 0xFB	11111100b : 0xFC : -4
00011010b : 0x1A	11100101b : 0xE5	11100110b : 0xE6 : -26
?	?	10110000b : 0xB0 : -?

- 0x01 to 0x7F positive byte, 0x80 to 0xFF negative byte
- 0x00000001 to 0x7FFFFFFF positive dword
- 0x80000000 to 0xFFFFFFFF negative dword

Architecture - CISC vs. RISC

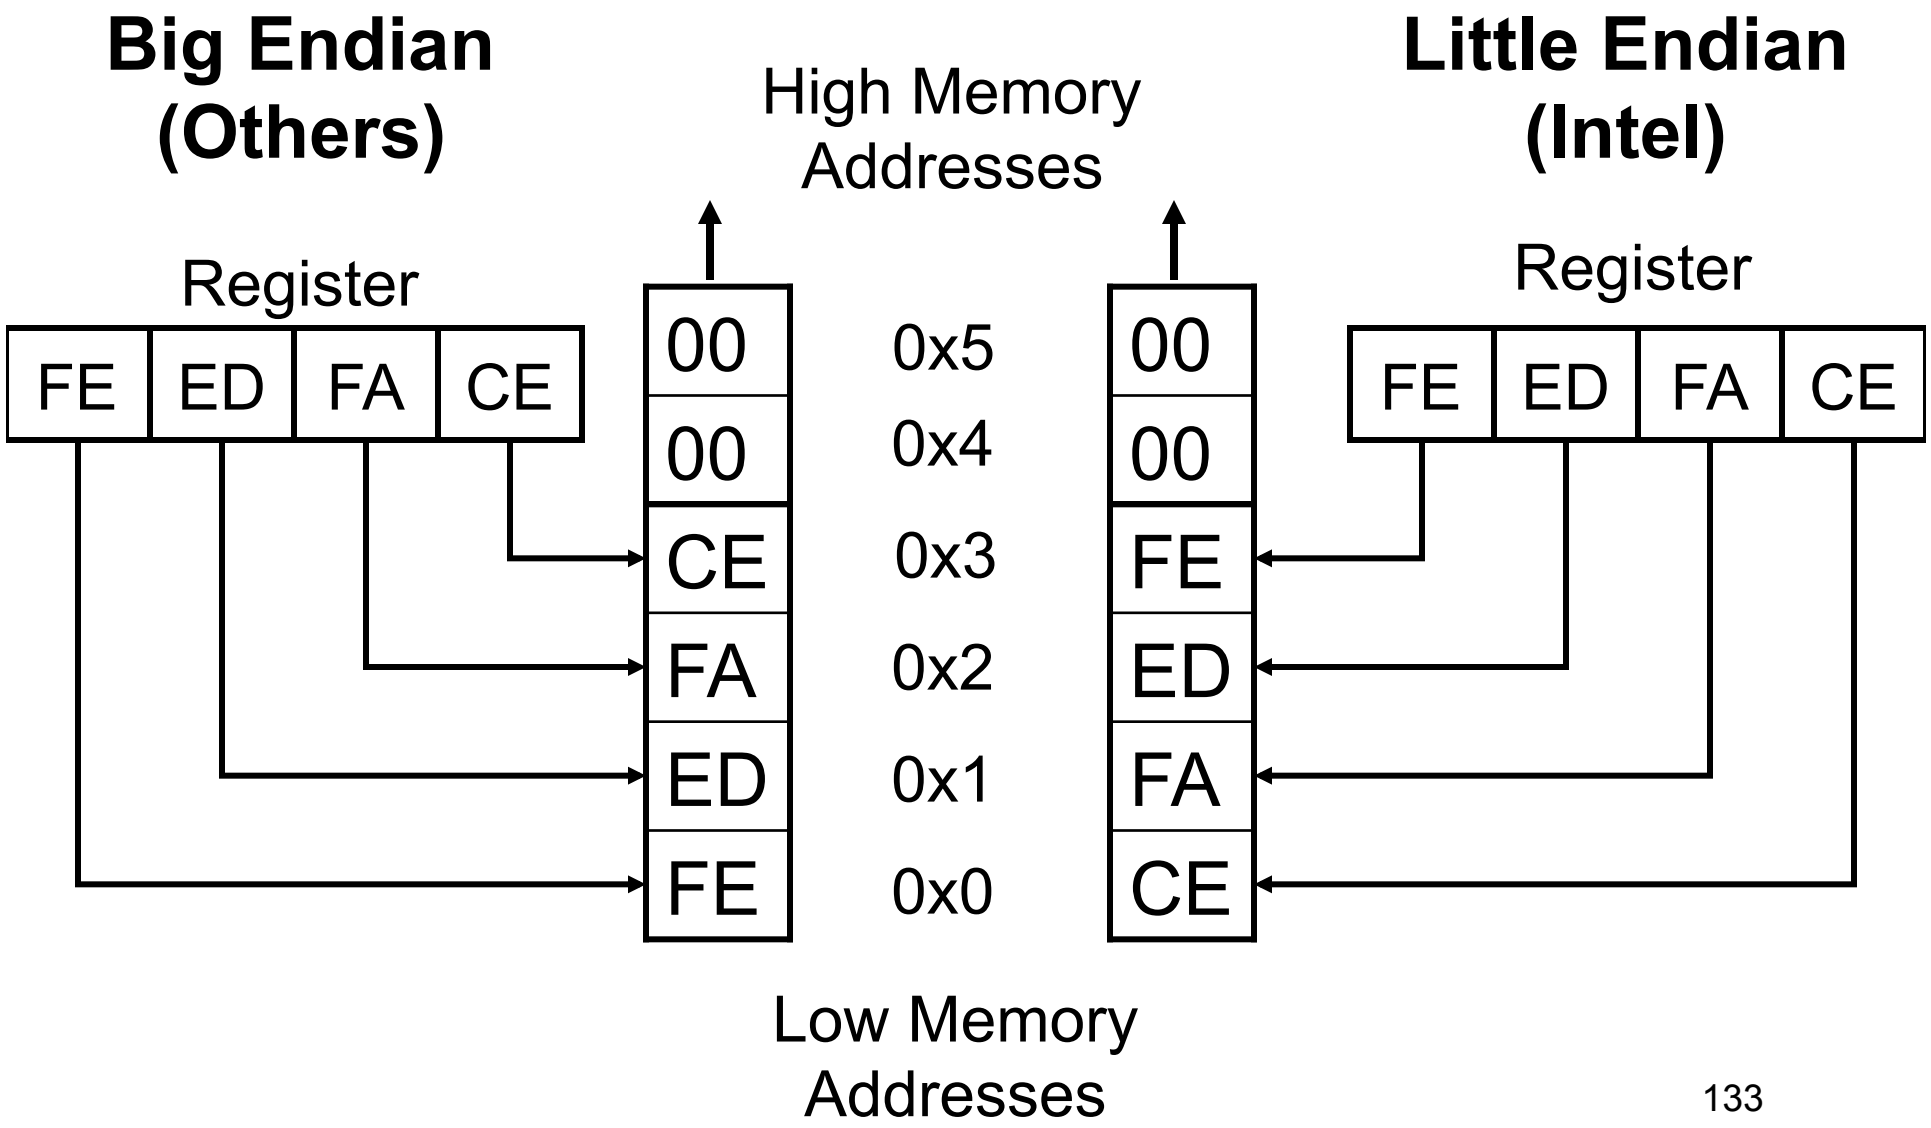
- Intel is CISC - Complex Instruction Set Computer
  - Many very special purpose instructions that you will never see, and a given compiler may never use - just need to know how to use the manual
  - Variable-length instructions, between 1 and 16(?) bytes long.
    - 16 is max len in theory, I don't know if it can happen in practice
- Other major architectures are typically RISC - Reduced Instruction Set Computer
  - Typically more registers, less and fixed-size instructions
  - Examples: PowerPC, ARM, SPARC, MIPS

Architecture - Endian

- Endianness comes from Jonathan Swift's *Gulliver's Travels*. It doesn't matter which way you eat your eggs :)
- Little Endian - 0x12345678 stored in RAM "little end" first. The least significant byte of a word or larger is stored in the lowest address. E.g. 0x78563412
  - Intel is Little Endian
- Big Endian - 0x12345678 stored as is.
  - Network traffic is Big Endian
  - Most everyone else you've heard of (PowerPC, ARM, SPARC, MIPS) is either Big Endian by default or can be configured as either (Bi-Endian)

Book p. 163

Endianess pictures



Architecture - Registers

- Registers are small memory storage areas built into the processor (still volatile memory)
- 8 “general purpose” registers + the instruction pointer which points at the next instruction to execute
  - But two of the 8 are not that general
- On x86-32, registers are 32 bits long
- On x86-64, they’re 64 bits

Book p. 25

Architecture - Register Conventions 1

- These are Intel's suggestions to compiler developers (and assembly handcoders). Registers don't have to be used these ways, but if you see them being used like this, you'll know why. But I simplified some descriptions. I also color coded as **GREEN** for the ones which we will actually see in *this* class (as opposed to future ones), and **RED** for not.
- **EAX** – Stores function return values
- **EBX** – Base pointer to the data section
- **ECX** – Counter for string and loop operations
- **EDX** – I/O pointer

Intel Arch v1 Section 3.4.1 - General-Purpose Registers

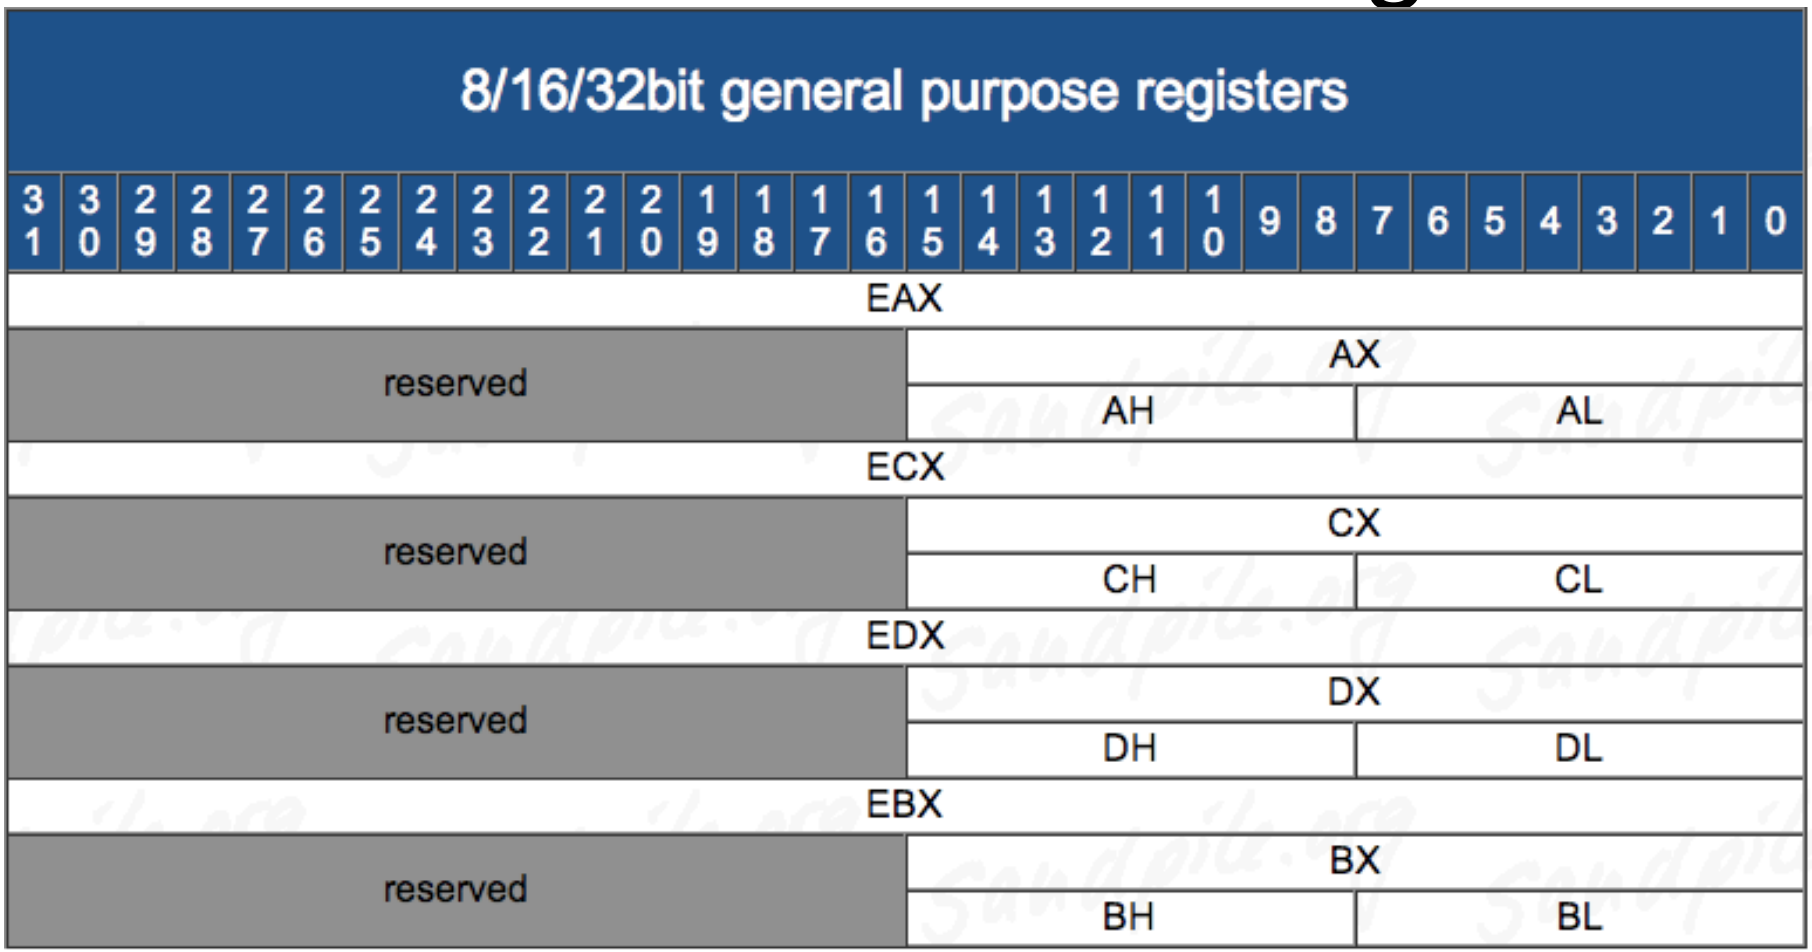
Architecture - Registers Conventions 2

- **ESI** – Source pointer for string operations
- **EDI** – Destination pointer for string operations
- **ESP** – Stack pointer
- **EBP** – Stack frame base pointer
- **EIP** - Pointer to next instruction to execute (“instruction pointer”)

Architecture - Registers Conventions 3

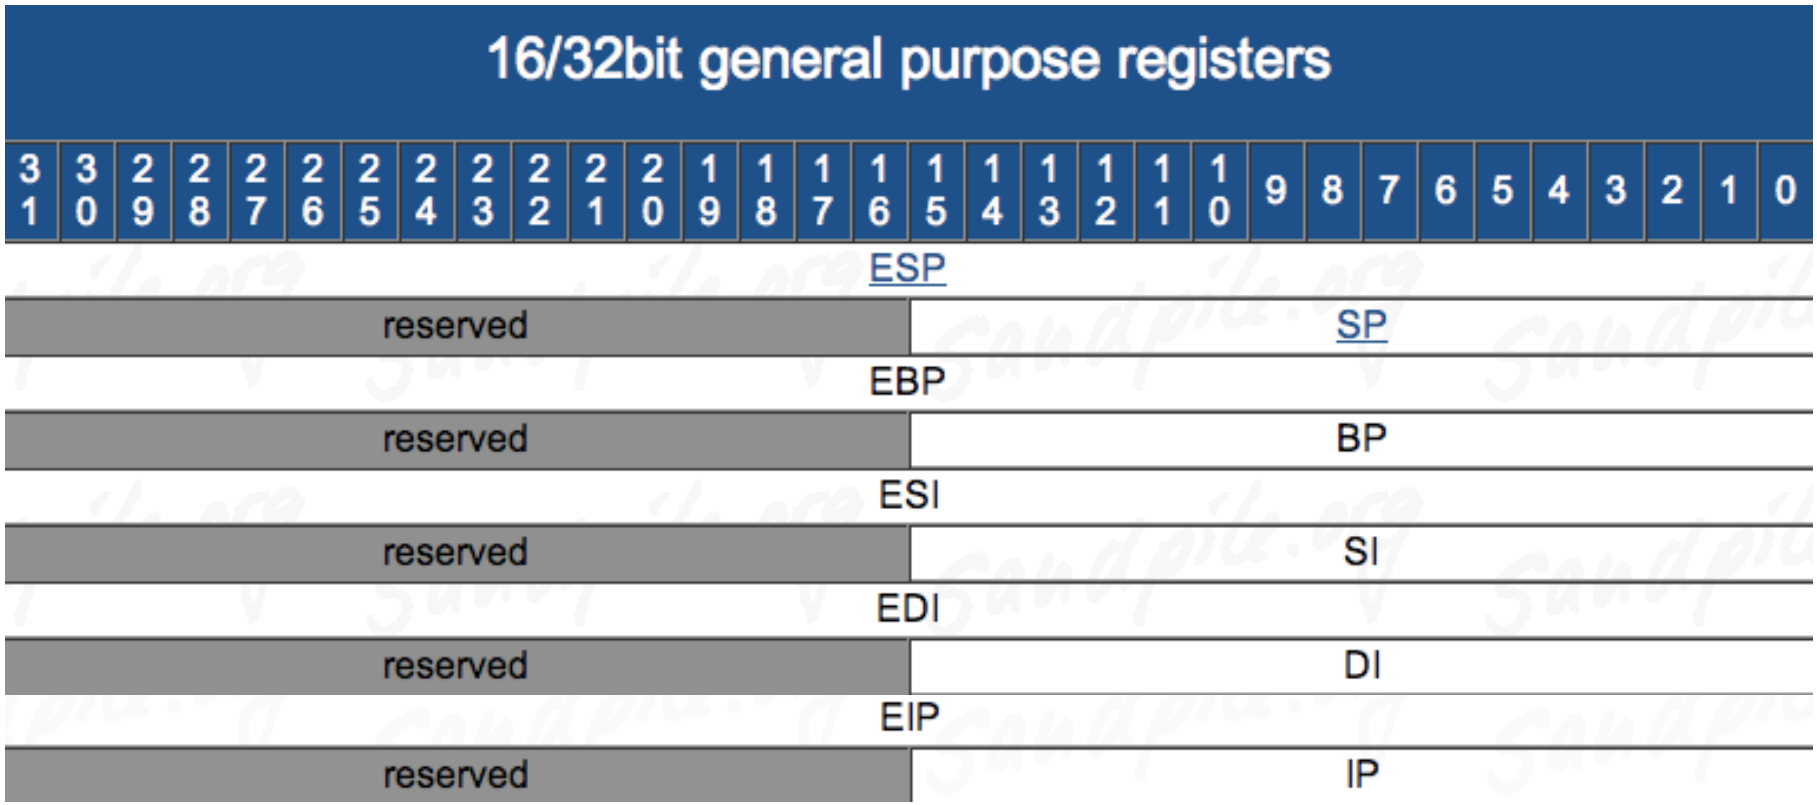
- Caller-save registers - eax, edx, ecx
  - If the caller has anything in the registers that it cares about, the caller is in charge of saving the value before a call to a subroutine, and restoring the value after the call returns
  - Put another way - the callee can (and is highly likely to) modify values in caller-save registers
- Callee-save registers - ebp, ebx, esi, edi
  - If the callee needs to use more registers than are saved by the caller, the callee is responsible for making sure the values are stored/restored
  - Put another way - the callee must be a good citizen and not modify registers which the caller didn't save, unless the callee itself saves and restores the existing values

Architecture - Registers - 8/16/32 bit addressing 1



http://www.sandpile.org/ia32/reg.htm

Architecture - Registers - 8/16/32 bit addressing 2



http://www.sandpile.org/ia32/reg.htm

Architecture - EFLAGS

- EFLAGS register holds many single bit flags. Will only ask you to remember the following for now.
  - Zero Flag (ZF) - Set if the result of some instruction is zero; cleared otherwise.
  - Sign Flag (SF) - Set equal to the most-significant bit of the result, which is the sign bit of a signed integer. (0 indicates a positive value and 1 indicates a negative value.)

Intel Vol 1 Sec 3.4.3 - page 3-20

Your first x86 instruction: NOP

- NOP - No Operation! No registers, no values, no nothin'!
- Just there to pad/align bytes, or to delay time
- Bad guys use it to make simple exploits more reliable. But that's another class ;)

Extra! Extra! Late-breaking NOP news!

- Amaze those who know x86 by citing this interesting bit of trivia:
- "The one-byte NOP instruction is an alias mnemonic for the XCHG (E)AX, (E)AX instruction."
  - I had never looked in the manual for NOP apparently :)
- Every other person I had told this to had never heard it either.
- Thanks to Jon Erickson for cluing me in to this.
- XCHG instruction is not officially in this class. But if I hadn't just told you what it does, I bet you would have guessed right anyway.

XCHG in book p. 112

The Stack

- The stack is a conceptual area of main memory (RAM) which is designated by the OS when a program is started.
  - Different OS start it at different addresses by convention
- A stack is a Last-In-First-Out (LIFO/FILO) data structure where data is "pushed" on to the top of the stack and "popped" off the top.
- By convention the stack grows toward lower memory addresses. Adding something to the stack means the top of the stack is now at a lower memory address.

The Stack 2

- As already mentioned, esp points to the top of the stack, the lowest address which is being used
  - While data will exist at addresses beyond the top of the stack, it is considered undefined
- The stack keeps track of which functions were called before the current one, it holds local variables and is frequently used to pass arguments to the next function to be called.
- A firm understanding of what is happening on the stack is ***essential*** to understanding a program's operation.

PUSH - Push Word, Doubleword or Quadword onto the Stack

- For our purposes, it will always be a DWORD (4 bytes).
  - Can either be an immediate (a numeric constant), or the value in a register
- The push instruction automatically decrements the stack pointer, esp, by 4.

Book p. 120

Registers Before

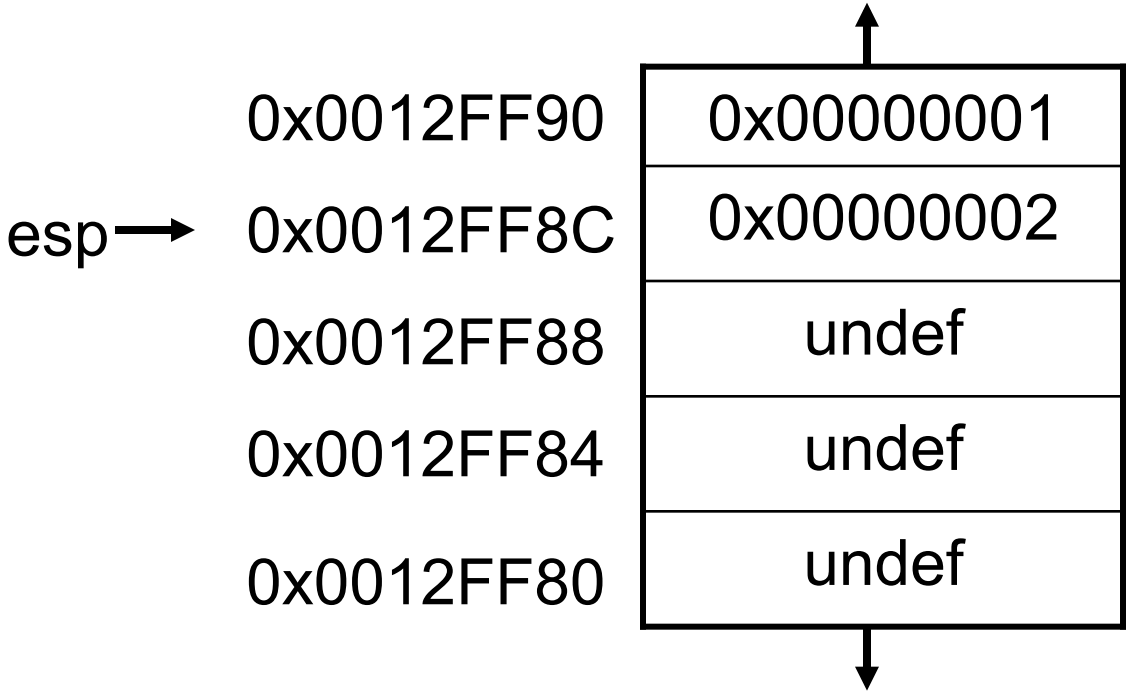
eax	0x00000003
esp	0x0012FF8C

push eax

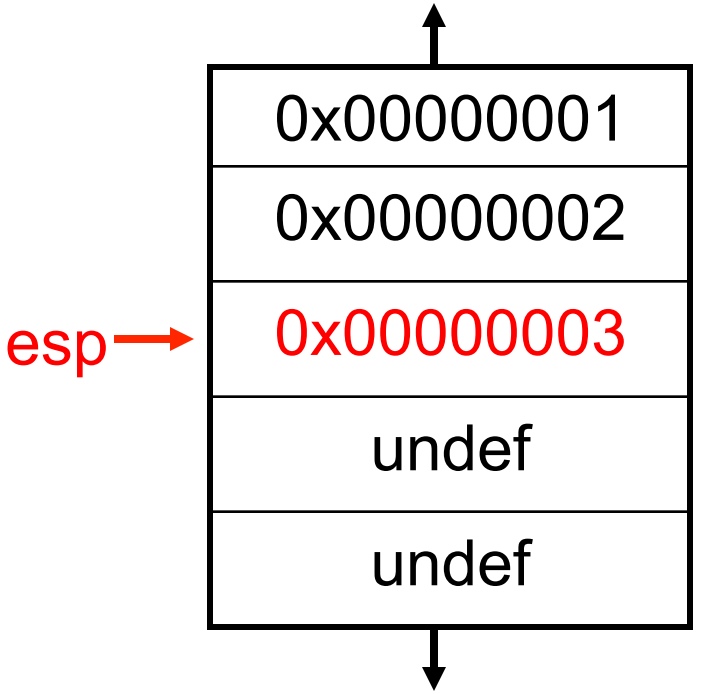
Registers After

eax	0x00000003
esp	0x0012FF88

Stack Before



Stack After



POP- Pop a Value from the Stack

- Take a DWORD off the stack, put it in a register, and increment esp by 4

Book p. 120

Calling Conventions

- How code calls a subroutine is compiler-dependent and configurable. But there are a few conventions.
- We will only deal with the “cdecl” and “stdcall” conventions.
- More info at
  - http://en.wikipedia.org/wiki/X86_calling_conventions
  - http://www.programmersheaven.com/2/Calling-conventions

Calling Conventions - cdecl

- “C declaration” - most common calling convention
- Function parameters pushed onto stack right to left
- Saves the old stack frame pointer and sets up a new stack frame
- eax or edx:eax returns the result for primitive data types
- Caller is responsible for cleaning up the stack

Calling Conventions - stdcall

- I typically only see this convention used by Microsoft C++ code - e.g. Win32 API
- Function parameters pushed onto stack right to left
- Saves the old stack frame pointer and sets up a new stack frame
- eax or edx:eax returns the result for primitive data types
- Callee responsible for cleaning up any stack parameters it takes
- Aside: typical MS, "If I call my new way of doing stuff 'standard' it must be true!"

CALL - Call Procedure

- CALL's job is to transfer control to a different function, in a way that control can later be resumed where it left off
- First it pushes the address of the next instruction onto the stack
  - For use by RET for when the procedure is done
- Then it changes eip to the address given in the instruction
- Destination address can be specified in multiple ways
  - Absolute address
  - Relative address (relative to the end of the instruction)

Book p. 132

RET - Return from Procedure

- Two forms
  - Pop the top of the stack into eip (remember pop increments stack pointer)
    - In this form, the instruction is just written as “ret”
    - Typically used by cdecl functions
  - Pop the top of the stack into eip and add a constant number of bytes to esp
    - In this form, the instruction is written as “ret 0x8”, or “ret 0x20”, etc
    - Typically used by stdcall functions

Kinda book p. 133

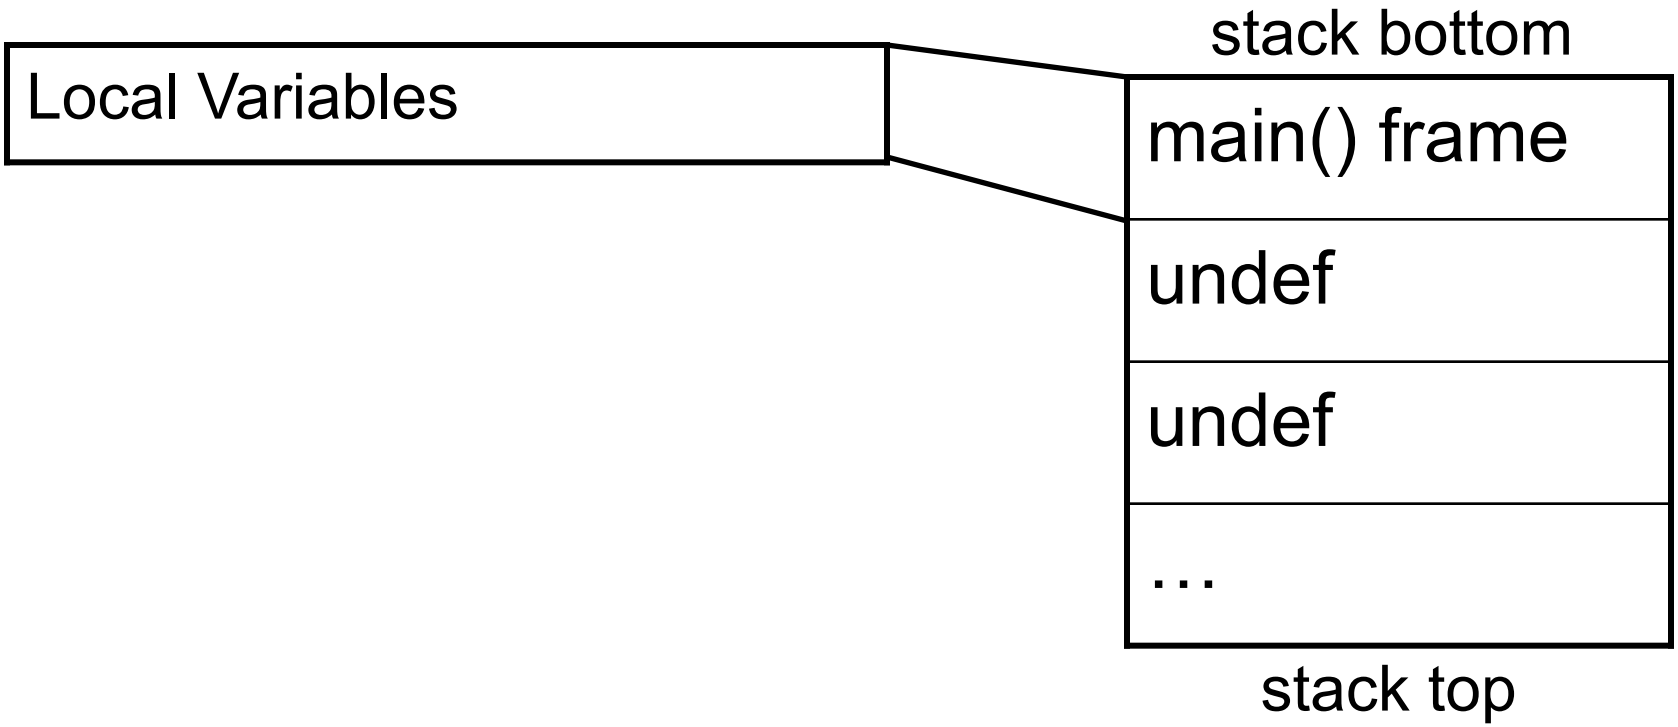
MOV - Move

- Can move:
  - register to register
  - memory to register, register to memory
  - immediate to register, immediate to memory
- Never memory to memory!
- Memory addresses are given in r/m32 form talked about later

Book p. 97

General Stack Frame Operation

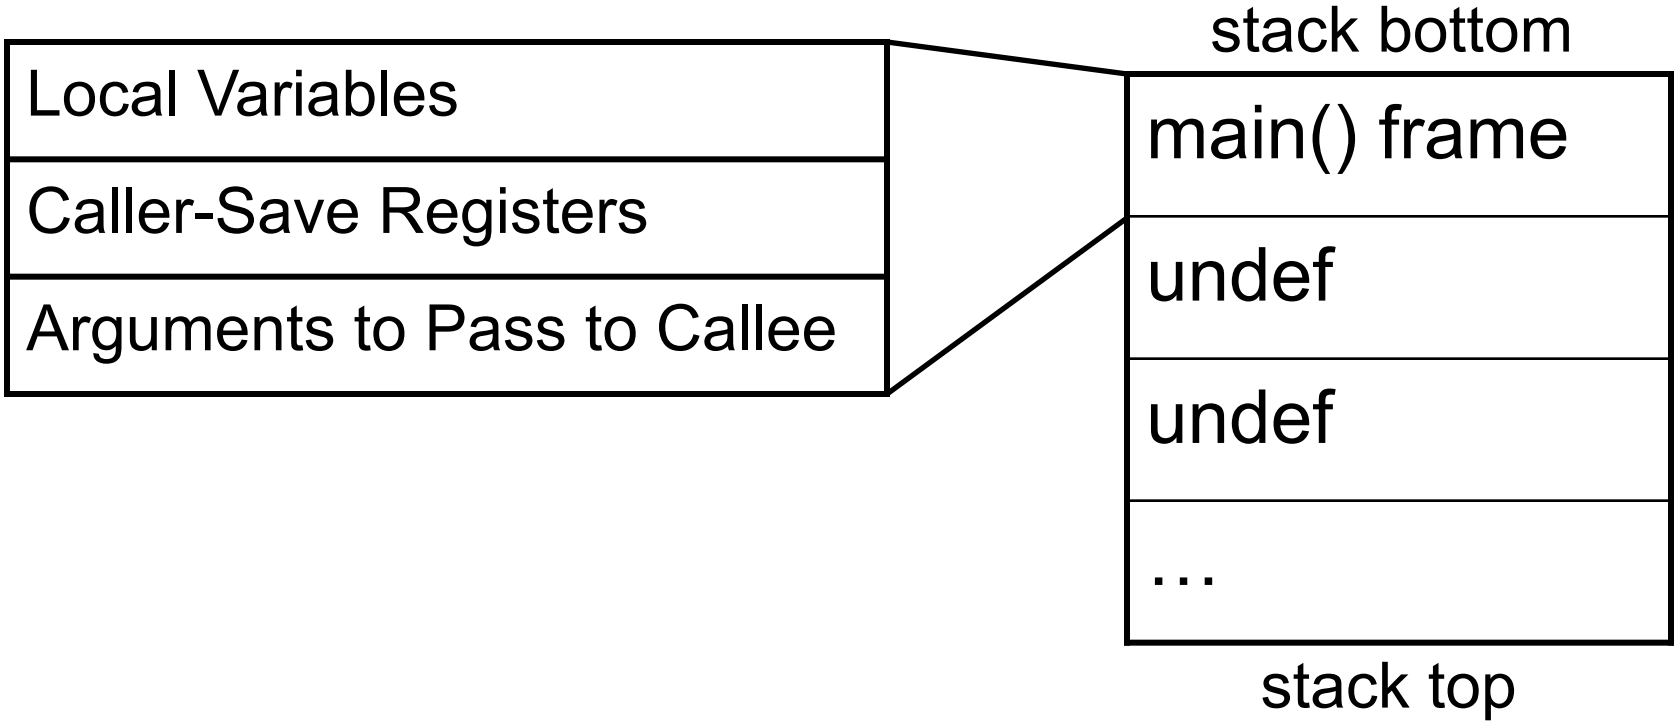
We are going to pretend that main() is the very first function being executed in a program. This is what its stack looks like to start with (assuming it has any local variables).



Book p. 306

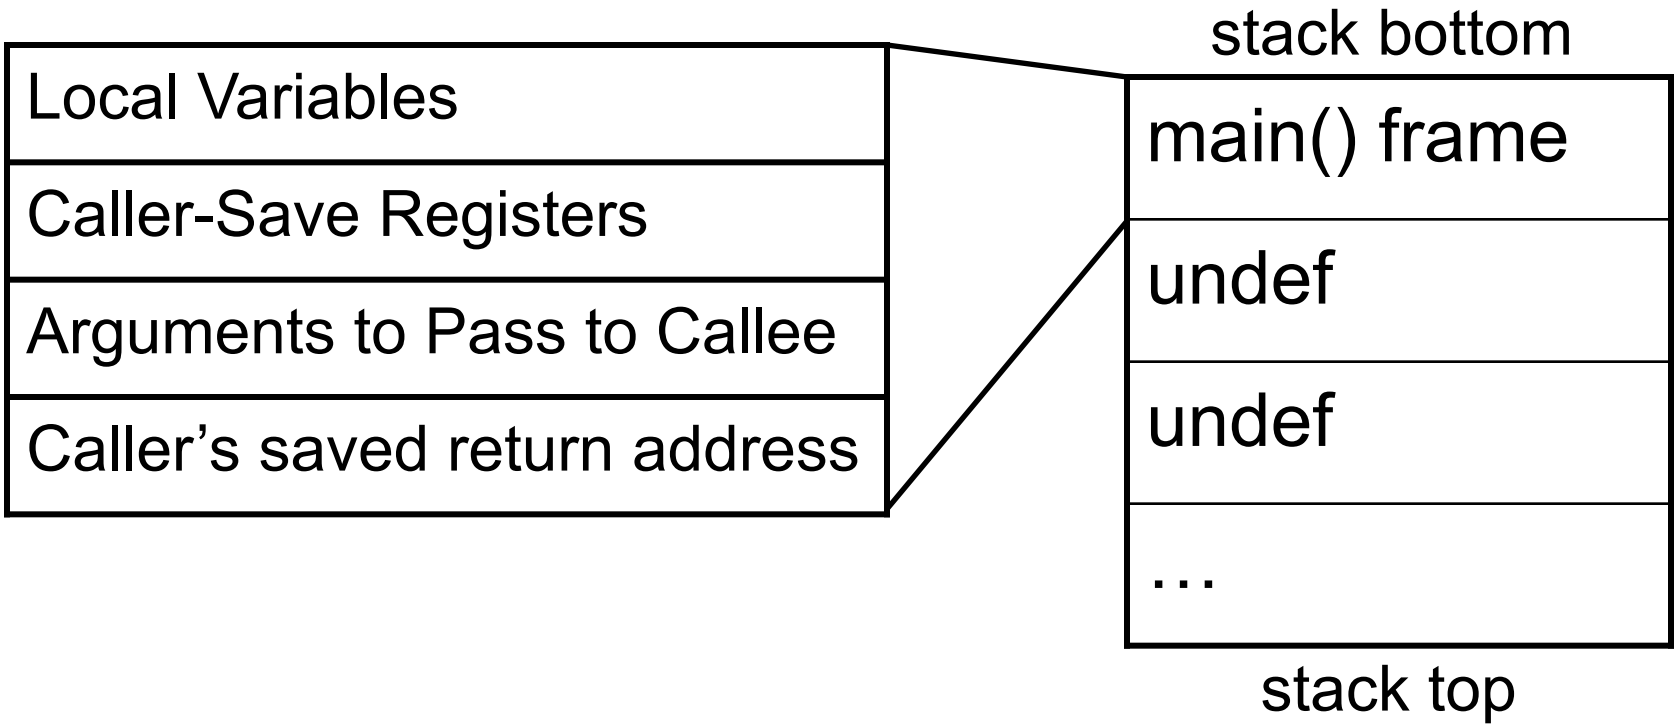
General Stack Frame Operation 2

When main() decides to call a subroutine, main() becomes “the caller”. We will assume main() has some registers it would like to remain the same, so it will save them. We will also assume that the callee function takes some input arguments.



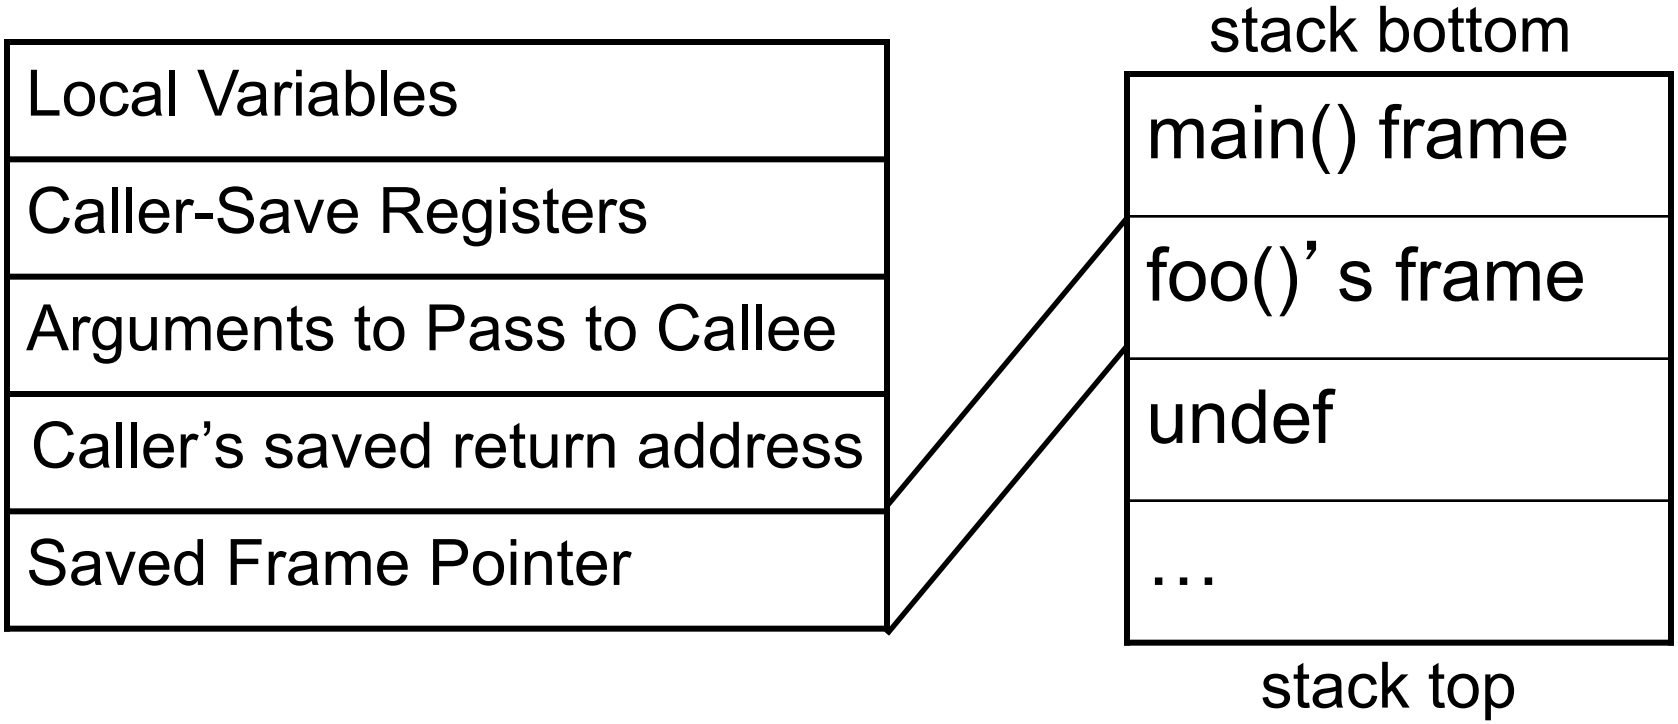
General Stack Frame Operation 3

When main() actually issues the CALL instruction, the return address gets saved onto the stack, and because the next instruction after the call will be the beginning of the called function, we consider the frame to have changed to the callee.



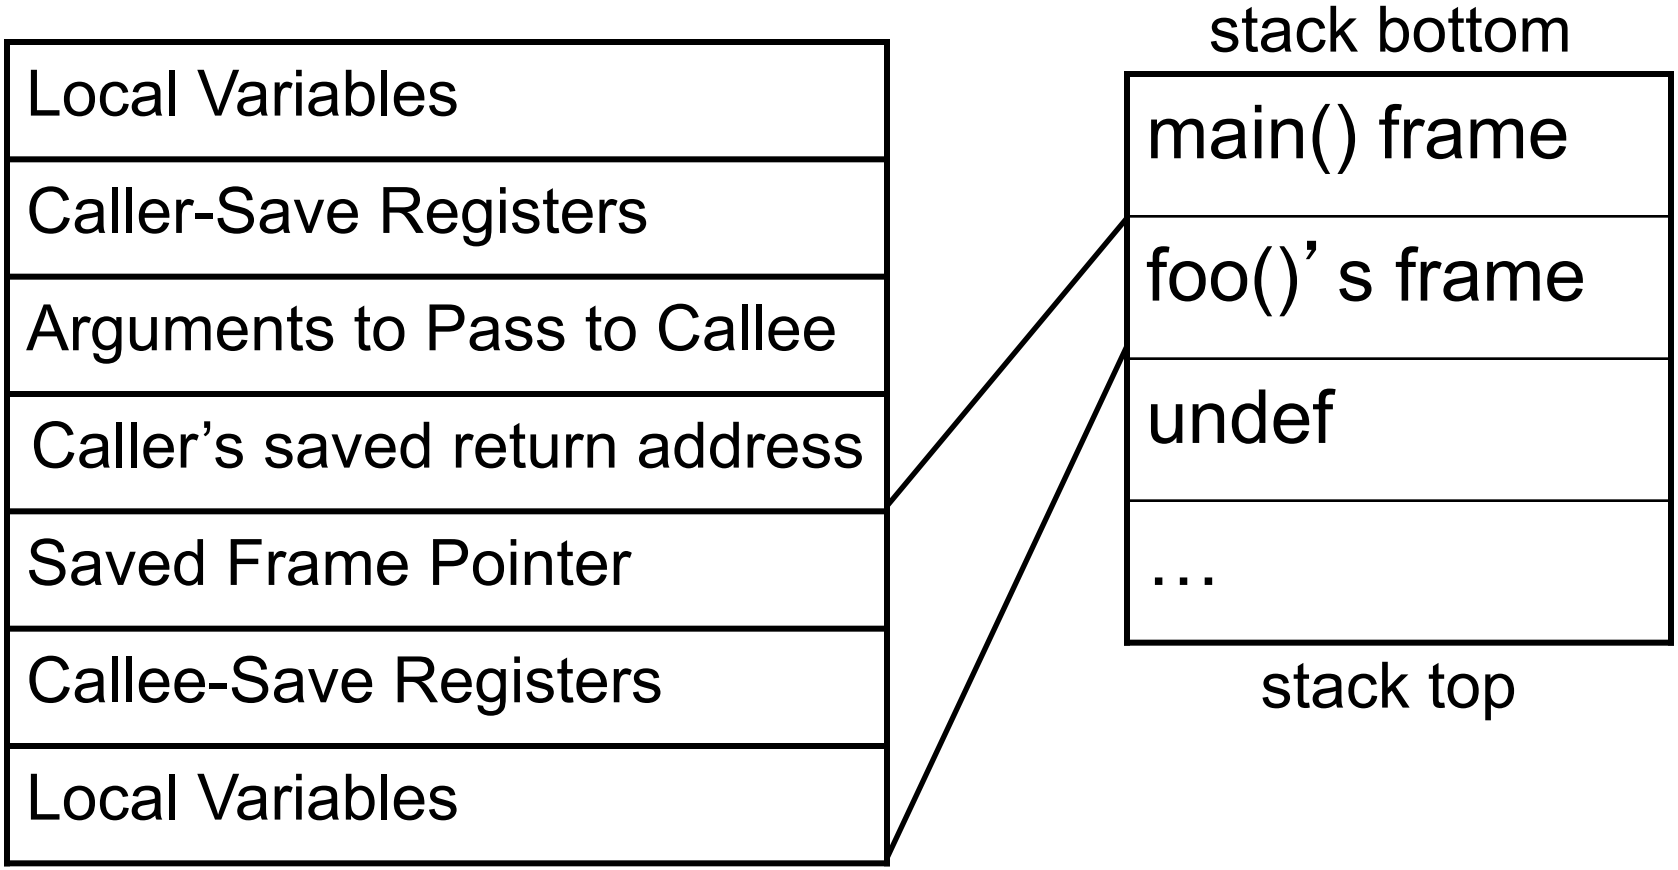
General Stack Frame Operation 4

When sub() starts, the frame pointer (ebp) still points to main()'s frame. So the first thing it does is to save the old frame pointer on the stack and set the new value to point to its own frame.



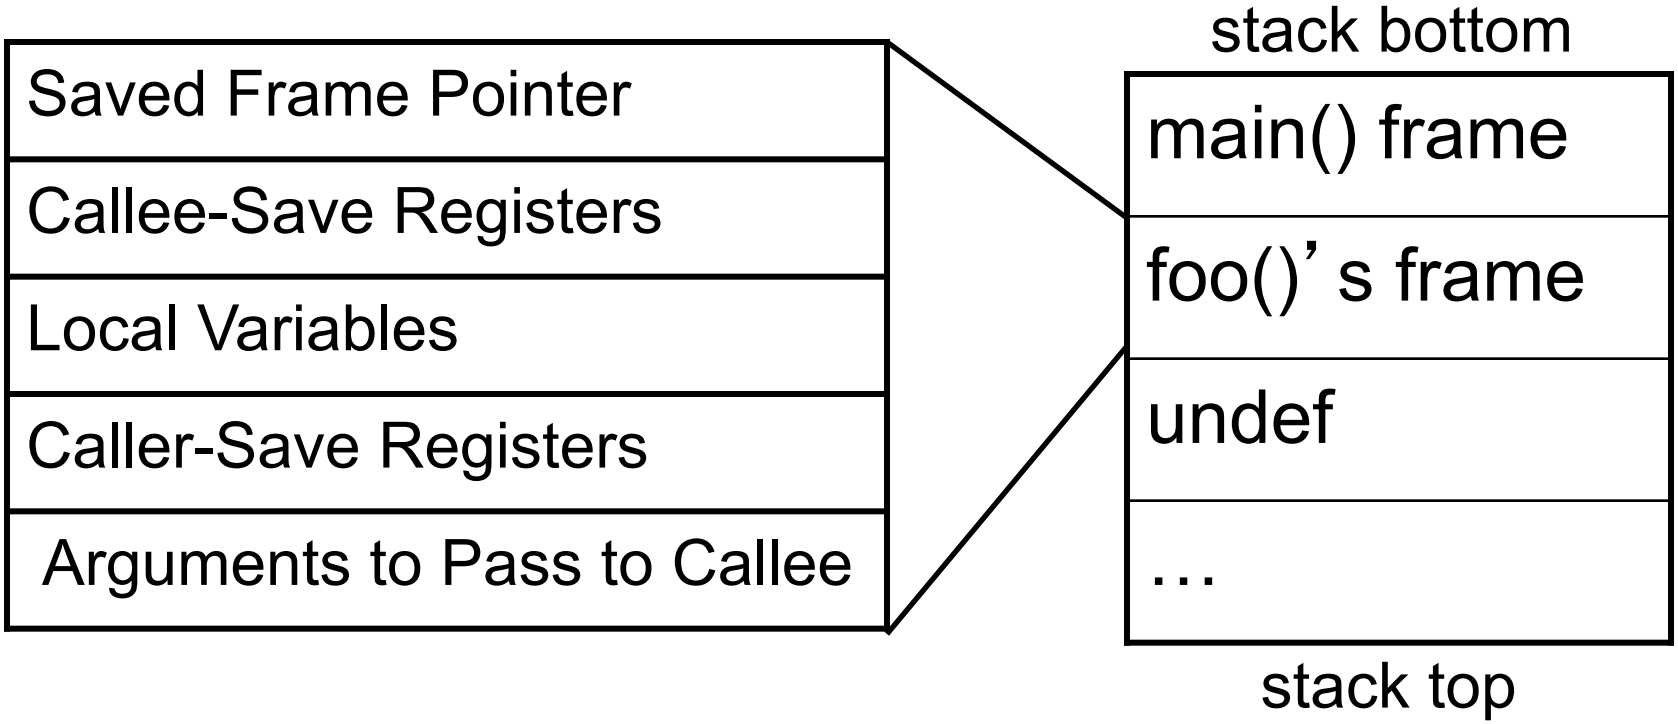
General Stack Frame Operation 5

Next, we'll assume the the callee sub() would like to use all the registers, and must therefore save the callee-save registers. Then it will allocate space for its local variables.



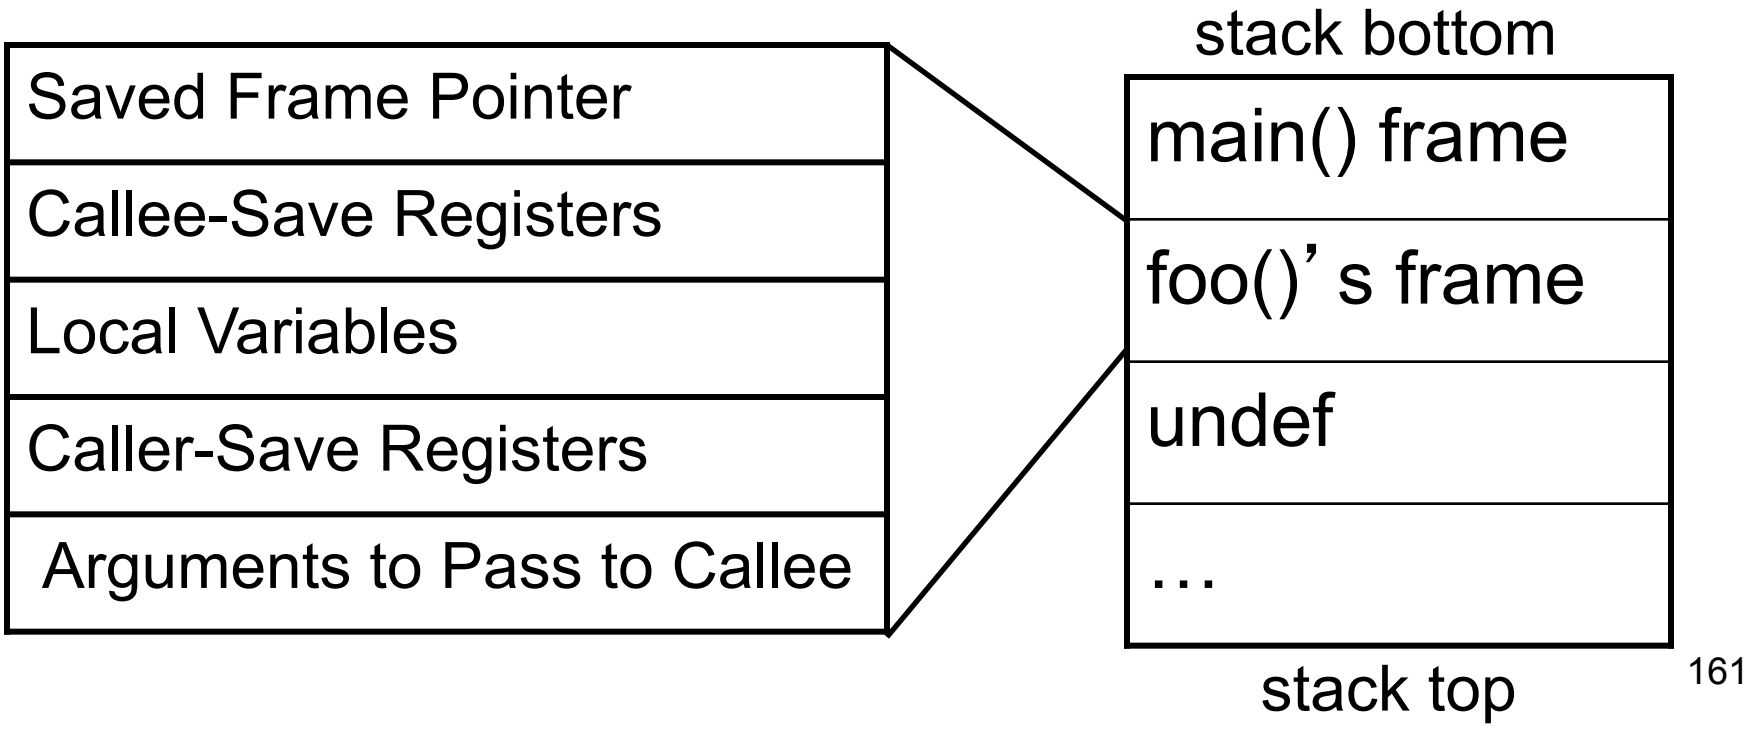
General Stack Frame Operation 6

At this point, foo() decides it wants to call bar(). It is still the callee-of-main (), but it will now be the caller-of-bar. So it saves any caller-save registers that it needs to. It then puts the function arguments on the stack as well.



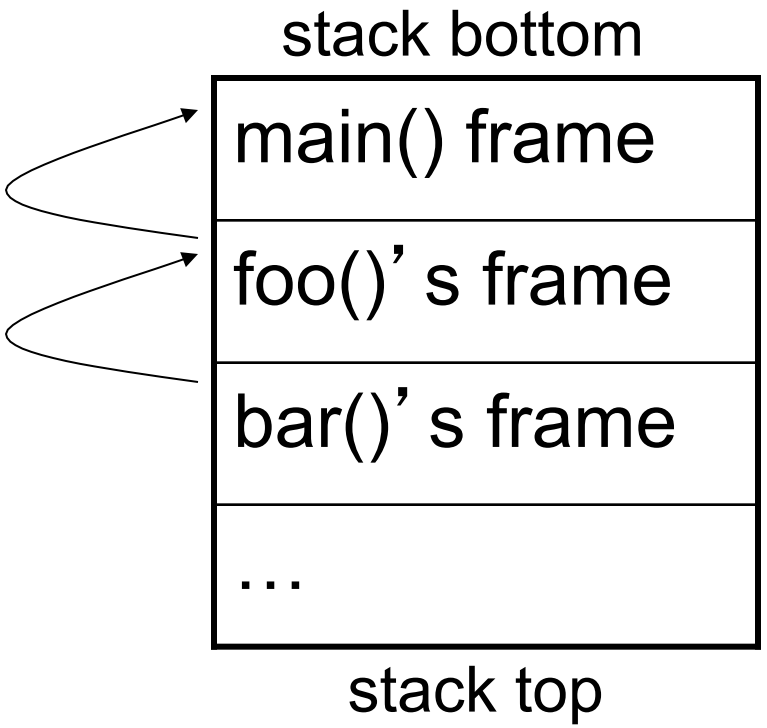
General Stack Frame Layout

Every part of the stack frame is technically optional (that is, you can hand code asm without following the conventions.)
But compilers generate code which uses portions if they are needed.
Which pieces are used can sometimes be manipulated with compiler options. (E.g. omit frame pointers, changing calling convention to pass arguments in registers, etc.)



Stack Frames are a Linked List!

The ebp in the current frame points at the saved ebp of the previous frame.



Example1.c

The stack frames in this example will be very simple.
Only saved frame pointer (ebp) and saved return addresses (eip).

```
//Example1 - using the stack
//to call subroutines
//New instructions:
//push, pop, call, ret, mov
int sub(){
    return 0xbeef;
}
int main(){
    sub();
    return 0xf00d;
}
```

```
sub:
00401000  push        ebp
00401001  mov         ebp,esp
00401003  mov         eax,0BEEFh
00401008  pop         ebp
00401009  ret
main:
00401010  push        ebp
00401011  mov         ebp,esp
00401013  call        sub (401000h)
00401018  mov         eax,0F00Dh
0040101D  pop         ebp
0040101E  ret
```

0040101D  pop         ebp
0040101E  ret ☒
```

Execution would continue at the value ret removed from the stack: 0x004012E8

Example1 Notes

- sub() is deadcode - its return value is not used for anything, and main always returns 0xF00D. If optimizations are turned on in the compiler, it would remove sub()
- Because there are no input parameters to sub (), there is no difference whether we compile as cdecl vs stdcall calling conventions

Let's do that in a tool

- Visual C++ 2008 Express Edition (which I will shorthand as "VisualStudio" or VS)
- Standard Windows development environment
- Available for free, but missing some features that pro developers might want
- Can't move applications to other systems without installing the "redistributable libraries"

Unfortunately the debug information format alters the code which gets generated too much, making it not as simple as I would like for this class.

Going through Example1.c in Visual Studio

```
sub:
  push      ebp
  mov       ebp,esp
  mov       eax,0BEEFh
  pop       ebp
  ret
main:
  push      ebp
  mov       ebp,esp
  call      sub
  mov       eax,0F00Dh
  pop       ebp
  ret
```

Example2.c with Input parameters and Local Variables

```
#include <stdlib.h>
int sub(int x, int y){
        return 2*x+y;
}

int main(int argc, char ** argv){
        int a;
        a = atoi(argv[1]);
        return sub(argc,a);
}
```

```
.text:00000000 _sub:      push    ebp
.text:00000001            mov     ebp, esp
.text:00000003            mov     eax, [ebp+8]
.text:00000006            mov     ecx, [ebp+0Ch]
.text:00000009            lea     eax, [ecx+eax*2]
.text:0000000C            pop     ebp
.text:0000000D            retn

.text:00000037            mov     esp, ebp
.text:00000039            pop     ebp
.text:0000003A            retn
```

r/m32 Addressing Forms

- Anywhere you see an r/m32 it means it could be taking a value either from a register, or a memory address.
- I'm just calling these "r/m32 forms" because anywhere you see "r/m32" in the manual, the instruction can be a variation of the below forms.
- In Intel syntax, most of the time square brackets [] means to treat the value within as a memory address, and fetch the value at that address (like dereferencing a pointer)
  - mov eax, ebx
  - mov eax, [ebx]
  - mov eax, [ebx+ecx*X] (X=1, 2, 4, 8)
  - mov eax, [ebx+ecx*X+Y] (Y= one byte, 0-255 or 4 bytes, 0-2^32-1)
- Most complicated form is: `[base + index*scale + disp]`

More info: Intel v2a, Section 2.1.5 page 2-4
in particular Tables 2-2 and 2-3

LEA - Load Effective Address

- Frequently used with pointer arithmetic, sometimes for just arithmetic in general
- Uses the r/m32 form but **is the exception to the rule** that the square brackets [ ] syntax means dereference (“value at”)
- Example: ebx = 0x2, edx = 0x1000
  - lea eax, [edx+ebx*2]
  - eax = 0x1004, not the value at 0x1004

Not covered in book

ADD and SUB

- Adds or Subtracts, just as expected
- Destination operand can be r/m32 or register
- Source operand can be r/m32 or register or immediate
- No source ***and*** destination as r/m32s, because that could allow for memory to memory transfer, which isn't allowed on x86
- Evaluates the operation as if it were on signed AND unsigned data, and sets flags as appropriate. Instructions modify OF, SF, ZF, AF, PF, and CF flags
- add esp, 8
- sub eax, [ebx*2]

Add p. 202, Sub p. 210

Example2.c - 1

```
.text:00000000 _sub:      push    ebp
.text:00000001            mov     ebp, esp
.text:00000003            mov     eax, [ebp+8]
.text:00000006            mov     ecx, [ebp+0Ch]
.text:00000009            lea     eax, [ecx+eax*2]
.text:0000000C            pop     ebp
.text:0000000D            retn

                        retn
```

Saving some slides…
This will push the address of the string at argv[1] (0x12FFD4). atoi() will read the string and turn in into an int, put that int in eax, and return. Then the adding 4 to esp will negate the having pushed the input parameter and make 0x12FF1C undefined again (this is indicative of cdecl)

                          pop    ebp
                          retn
```

First setting "a" equal to the return value. Then pushing "a" as the second parameter in sub(). We can see an obvious optimization would have been to replace the last two instructions with "push eax".
