### SMI Suppression

- SMM stands as the first line of defense for protecting the BIOS flash from being overwritten
  - We'll cover how in the flash BIOS portion of the course
- What if the attacker simply suppressed SMI from being generated?
- They can, if the system isn't locked down properly:

SMI_EN—SMI Control and Enable Register									
I/O Address: Default Value: Lockable: Power Well:	PMBASE + 30h 00000000h No Core	Attribute: Size: Usage:	R/W, R/WO, WO 32 bit ACPI o <mark>r Legacy</mark>						

I/O Controller Hub Family 9

### SMI\_EN: SMI Control and Enable Register

SMI_EN-SMI Contro	l and Enable Register
-------------------	-----------------------

I/O Address:	PMBASE + 30h	Attribute:	R/W, R/WO, WO
Default Value:	00000000h	Size:	32 bit
Lockable: Power Well:	No Core	Usage:	ACPI o <mark>r Legacy</mark>

#### GBL\_SMI\_EN - R/W.

0

0 = No SMI# will be generated by ICH9. This bit is reset by a PCI reset event.
 1 = Enables the generation of SMI# in the system upon any enabled SMI event.
 NOTE: When the SMI\_LOCK bit is set, this bit cannot be changed.

- Located in the Power Management IO Registers (memory-mapped at PMBASE defined in LPC D31:F0)
- The SMI\_EN register can enable or disable some very specific instances of SMI# or globally enable/disable all SMI#
- Shown above is the Global Enable/Disable for SMI#

# SMI\_EN

APMC\_EN - R/W.

- 0 = Disable. Writes to the APM\_CNT register will not cause an SMI#.
- 1 = Enables writes to the APM\_CNT register to cause an SMI#.

 $SLP_SMI_EN - R/W.$ 

- 0 = Disables the generation of SMI# on SLP\_EN. Note that this bit must be 0 before the software attempts to transition the system into a sleep state by writing a 1 to the SLP\_EN bit.
- 1 = A write of 1 to the SLP\_EN bit (bit 13 in PM1\_CNT register) will generate an SMI#, and the system will not transition to the sleep state based on that write to the SLP\_EN bit.

**LEGACY\_USB\_EN** - R/W.

0 = Disable.

1 = Enables legacy USB circuit to cause SMI#.

#### **BIOS\_EN** - R/W.

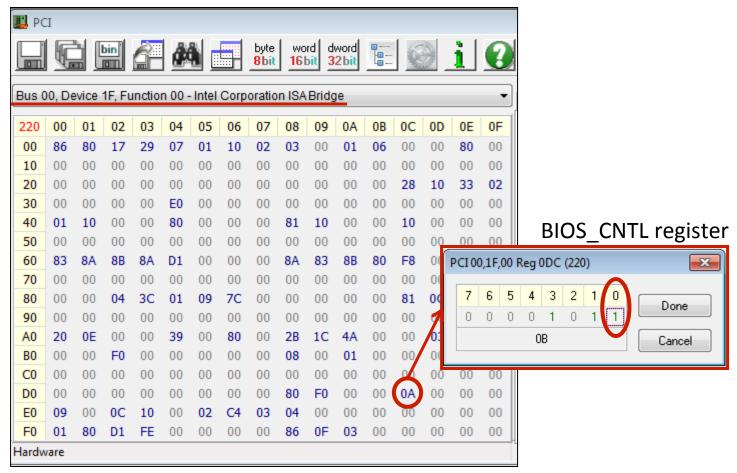

0 = Disable.

- 1 = Enables the generation of SMI# when ACPI software writes a 1 to the GBL\_RLS bit (D31:F0:PMBase + 04h:bit 2). Note that if the BIOS\_STS bit (D31:F0:PMBase + 34h:bit 2), which gets set when software writes 1 to GBL\_RLS bit, is already a 1 at the time that BIOS\_EN becomes 1, an SMI# will be generated when BIOS\_EN gets set.
- We can disable the generation of SMI# on writes to IO port 0xB2
- And a slough of others (BIOS\_EN refers to BIOS being able to receive ACPI "messages", it has nothing to do with enabling/ disabling BIOS itself)

# SMI\_EN

	GPIO_UNLOCK_SMI_EN— R/WO. Setting this bit will cause the Intel ICH9 to generate an SMI# when the GPIO_UNLOCK_SMI_STS bit is set in the SMI_STS
27	register.
	Once written to `1', this bit can only be cleared by PLTRST#.
26:19	Reserved
	INTEL_USB2_EN - R/W.
18	0 = Disable
	1 = Enables Intel-Specific USB2 SMI logic to cause SMI#.
	LEGACY_USB2_EN - R/W.
17	0 = Disable
	1 = Enables legacy USB2 logic to cause SMI#.
16:15	Reserved
	PERIODIC_EN - R/W.
14	0 = Disable.
	1 = Enables the ICH9 to generate an SMI# when the PERIODIC_STS bit (PMBASE + 34h, bit 14) is set in the SMI_STS register (PMBASE + 34h).
	TCO_EN - R/W.
13	<ul> <li>0 = Disables TCO logic generating an SMI#. Note that if the NMI2SMI_EN bit is set, SMIs that are caused by re-routed NMIs will not be gated by the TCO_EN bit. Even if the TCO_EN bit is 0, NMIs will still be routed to cause SMIs.</li> <li>1 = Enables the TCO logic to generate SMI#.</li> </ul>
	NOTE: This bit cannot be written once the TCO_LOCK bit is set.
12	Reserved
	MCSMI_ENMicrocontroller SMI Enable (MCSMI_EN) — R/W.
	0 = Disable.
11	1 = Enables ICH9 to trap accesses to the microcontroller range (62h or 66h) and generate an SMI#. Note that "trapped' cycles will be claimed by the ICH9 on PCI, but not forwarded to LPC.

- SMI\_EN provides a lot of control over the generation of SMI#
- It can also enable/disable that periodic generation of SMI#
- You get the idea...

- As we know, we (should be) unable to assert bit 0 in the BIOS\_CNTL register located in LPC D31:F0, offset DCh
- Let's "fix" that!

#### PMBASE—ACPI Base Address Register (LPC I/F—D31:F0)

Offset Address:	40h-43h	Attribute:	R/W, RO
Default Value:	0000001h	Size:	32 bit
Lockable:	No	Usage: Power Well:	ACPI, Legacy Core

Sets base address for ACPI I/O registers, GPIO registers and TCO I/O registers. These registers can be mapped anywhere in the 64-K I/O space on 128-byte boundaries.

Bit	Description
31:16	Reserved
15:7	<b>Base Address</b> — R/W. This field provides 128 bytes of I/O space for ACPI, GPIO, and TCO logic. This is placed on a 128-byte boundary.
6:1	Reserved
0	Resource Type Indicator (RTE) — RO. Hardwired to 1 to indicate I/O space.

- Locate the PMBASE address from LPC D31:F0, offset 40h
- This is mapped to the I/O address space, as indicated in the Base Address register description

				90	FFFF	FFFF	F					F
				A0	FFFF	FFFF	FFFF	FFFF	FFFF	FFFF	FFFF	FFFF

- In this case we can see it is mapped to I/O starting at address 0x1000
- Open up an I/O ports window and enter 0x1000
- Be sure to check ACPI Power Management Base
- On some systems not doing this causes lockups or system crashes

#### SMI\_EN—SMI Control and Enable Register

I/O Address: Default Value: Lockable: Power Well:	PMBASE + 30h 00000000h No Core	Attribute: Size: Usage:	R/W, R/WO, WC 32 bit ACPI o <mark>r Legacy</mark>
Power well:	Core		

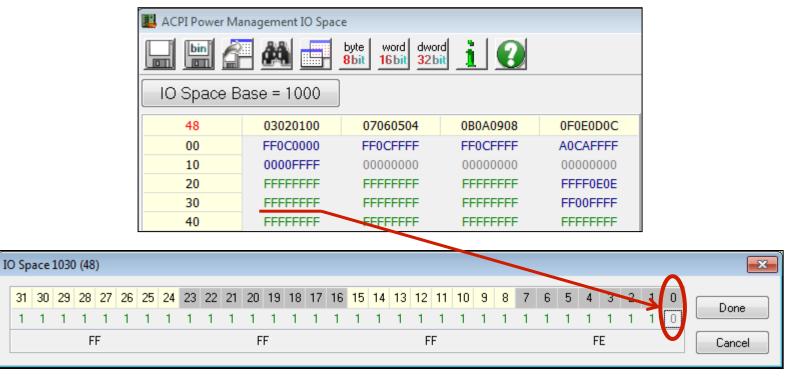

GBL\_SMI\_EN - R/W.

0 = No SMI# will be generated by ICH9. This bit is reset by a PCI reset event. 1 = Enables the generation of SMI# in the system upon any enabled SMI event. **NOTE:** When the SMI\_LOCK bit is set, this bit cannot be changed.

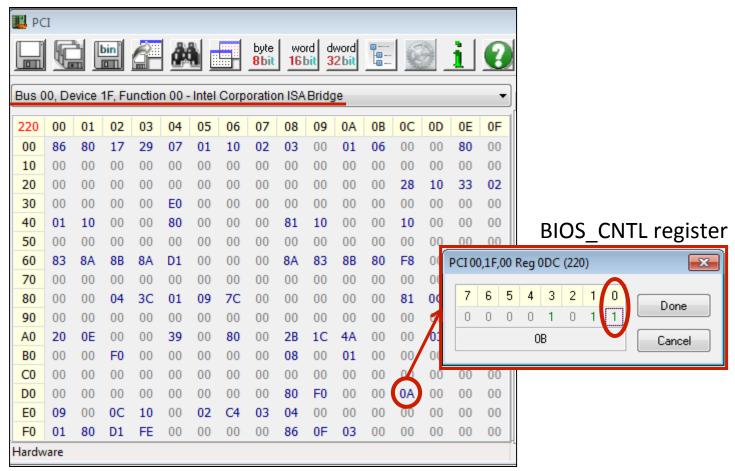

🕌 ACPI Power Management IO Space

00	FF0C0000	FF0CFFFF	FF0CFFFF	A0CAFFFF		
10	0000FFFF	00000000	00000000	00000000		
20		FFFFFFF	FFFFFFF	FFFF0E0E		
30	FFFFFFF	FFFFFFF	FFFFFFF	FF00FFFF		
40	FFFFFFF	FFFFFFF	FFFFFFF	FFFFFFF		

- The bit to suppress global SMI# is at bit 0 in the SMI\_EN register located at PMBASE + 30h
- It looks like uninitialized space, but everything is enabled
- Just not locked down

0

- Commence SMI# suppression!
- De-assert bit 0 so that SMI\_EN is FFFF\_FFEh

- Now with SMI# suppressed we can enable writes to the BIOS flash by asserting bit 0 in the BIOS\_CNTL register
- · We'll cover this in more detail in the next section

Hardw	are															

- Notice that bit 0 remains asserted now whereas before disabling SMI# it would have been reset to 0
- Now we can write to the BIOS. This is very bad.

 Running the write\_bios\_base\_deadbeef.sys writes to the BIOS base to prove this point

# Demo Video: Charizard

- Ring0 can modify <u>authenticated</u> EFI Variables, which allows trivial bypassing of Secure Boot
  - We'll cover this in the UEFI secure boot portion of the class. For now just take my word for it: this is not good

# SMI Suppression

- As we'll see in the next section, there is one secondary defense that could still work to prevent an attacker from being able to flash the BIOS under these circumstances
  - However they can't be used to protect the UEFI variables because those must <u>always be writeable</u>
- Locking down the SMI\_EN register is something that vendors don't really know about:
- 3216 of 8005 (~40%) systems measured did not have SMI\_LOCK set
  - The numbers are much higher if you rollback the BIOS to a vulnerable revision, which is typically permitted

#### SMI Suppression Prevention 1: GEN\_PMCON1

#### GEN\_PMCON\_1-General PM Configuration 1 Register (PM-D31:F0)

Offset Address: A0h Default Value: 0000h Lockable: No Attribute: Size: Usage: Power Well: R/W, RO, R/WO 16-bit ACPI, Legacy Core

4	SMI_LOCK — R/WO. When this bit is set, writes to the GLB_SMI_EN bit (PMBASE + 30h, bit 0) will have no effect. Once the SMI_LOCK bit is set, writes of 0 to SMI_LOCK bit will have no effect (i.e., once set, this bit can only be cleared by PLTRST#).
---	--

- GEN\_PMCON1 is located in the LPC D31:F0 Power Management registers
- The vendor must (must must!) assert SMI\_LOCK in the GEN\_PMCON\_1 register
- Don't give attackers the option of suppressing SMI#
- Especially since the system depends on SMM to protect the BIOS Flash!!!

#### SMI Suppression Prevention 2: BIOS\_CNTL.SMM\_BWP

#### 13.1.32 BIOS\_CNTL-BIOS Control Register (LPC I/F-D31:F0)

Offset Address:	DCh	Attribute:	R/WLO, R/W, RO
Default Value:	20h	Size:	8 bit
Lockable:	No	Power Well:	Core

Bit	Description	
7:6	Reserved	
5	<ul> <li>SMM BIOS Write Protect Disable (SMM_BWP)— R/WLO.</li> <li>This bit set defines when the BIOS region can be written by the host.</li> <li>0 = BIOS region SMM protection is disabled. The BIOS Region is writable regardless processors are in SMM or not. (Set this field to 0 for legacy behavior)</li> <li>1 = BIOS region SMM protection is enabled. The BIOS Region is not writable unless a processors are in SMM.</li> </ul>	

- We'll cover this register during the BIOS flash portion of the course
- Raises the security level of the platform
- Suffice to say this is a very useful (newish) feature
  - That isn't utilized very often
